Teaching Strategy If you have a variety of bar magnets, have the class compare results after finishing the activity. Ask students why the paper clips need to be the same size. *so you can compare the numbers picked up*

Think Critically

The two ends of the magnet exert the strongest attraction. The middle exerts a weaker attraction. Some magnets will not hold any clips there.

Assessment

Process Have students sketch a graph showing how the strength of the magnetic field changes over the length of the magnet. Use **Performance Assessment in the Science Classroom**, p. 127.

Magnetic Appeal

14

You might think of magicians when you hear the word levitation, but scientists can levitate, too! This photo shows a magnet levitating over a ceramic plate. Magnetic levitation has applications ranging from advertising displays to high-speed trains.

1. What happens as you move a magnet closer to a refrigerator door?
2. How do people use magnets in their daily lives?

L2

Reading Guide

What You'll Learn

- **Explain** how a magnet exerts a force.
- **Describe** the properties of temporary and permanent magnets.
- **Explain** why some materials are magnetic and some are not.
- **Model** magnetic behavior using magnetic domains.

Why It's Important

Without the forces exerted by magnets, you could not use televisions, computers, CD players, or even refrigerators.

Review Vocabulary

electric field: surrounds an electric charge and exerts a force on other electric charges

New Vocabulary

- magnetism
- magnetic field
- magnetic pole
- magnetic domain

Magnets

More than 2,000 years ago, Greeks discovered deposits of a mineral that was a natural magnet. They noticed that chunks of this mineral could attract pieces of iron. This mineral was found in a region of Turkey that then was known as Magnesias, so the Greeks called the mineral magnetic. The mineral is now called magnetite. In the twelfth century, Chinese sailors used magnetite to make compasses that improved navigation. Since then, many devices have been developed that rely on magnets to operate. Today, the word **magnetism** refers to the properties and interactions of magnets. **Figure 1** shows a device you might be familiar with that uses magnets and magnetism.

Figure 1 Magnets can be found in many devices you use every day, such as TVs, video games, and telephones. Headphones and CD players also contain magnets.

Magnetic Force You probably have played with magnets and noticed that two magnets exert a force on each other. Depending on which ends of the magnets are close together, magnets either repel or attract each other. You might have noticed that the interaction between two magnets can be felt even before the magnets touch. The strength of the force between two magnets increases as magnets move closer together and decreases as the magnets move farther apart.

Reading Check

What does the force between two magnets depend on?

Reading Preview

Tie to Prior Knowledge

Magnets Discuss with students places where they have used magnets. Most have used magnets on refrigerator doors. Explain that magnets are also used in such items as stereo speakers, televisions, and floppy disks.

Word Map Post the new vocabulary words in a prominent place in the classroom. Give students a sentence using each term. Ask them to determine the meaning of the word from the context of the sentence. Have students verify their ideas using the definitions in the text.

Figure 2 A magnet is surrounded by a magnetic field.

A magnet's magnetic field is represented by magnetic field lines.

Iron filings sprinkled around a magnet line up along the magnetic field lines.

Magnetic Field A magnet is surrounded by a magnetic field. A **magnetic field** exerts a force on other magnets and objects made of magnetic materials. The magnetic field is strongest close to the magnet and weaker farther away. The magnetic field can be represented by lines of force, or magnetic field lines. **Figure 2** shows the magnetic field lines surrounding a bar magnet. A magnetic field also has a direction. The direction of the magnetic field around a bar magnet is shown by the arrows on the left side of **Figure 2**.

Magnetic Poles Look again at **Figure 2**. Do you notice that the magnetic field lines are closest together at the ends of the bar magnet? These regions, called the **magnetic poles**, are where the magnetic force exerted by the magnet is strongest. All magnets have a north pole and a south pole. For a bar magnet, the north and south poles are at the opposite ends.

Figure 3 shows the north and south poles of magnets with more complicated shapes. The two ends of a horseshoe-shaped magnet are the north and south poles. A magnet shaped like a disk has opposite poles on the top and bottom of the disk. Magnetic field lines always connect the north pole and the south pole of a magnet.

Figure 3 The magnetic field lines around horseshoe and disk magnets begin at each magnet's north pole and end at the south pole.

Identify where the magnetic field is strongest.

✓ Reading Check

Answer the distance between the two magnets

Use an Analogy

Earth's Attraction A magnet's field, like a gravitational field, affects objects without touching them, even at a great distance. The faraway north magnetic pole attracts a compass needle, like the distant Sun holds Earth in orbit.

Use Science Words

Word Meaning Have students find out what *field* means in physics. A **field** is a region of space with a physical property (such as gravitational force, fluid pressure, etc.) that has a definite value at every point in the region. Compare and contrast this with other meanings of *field*. Other meanings also refer to areas, such as a meadow, a playing field, a background region, or even an area of interest. [L3]

Linguistic

Activity

Magnets Divide the class into small groups and provide each group with a set of magnets. Allow students to observe the properties and behaviors of the magnets. [L1]

Caption Answer

Figure 3 at the magnetic poles

Reading Strategy

Brainstorm Give students a statement that summarizes the content of each section and ask them to brainstorm words related to the statement. For example, provide the summary statement, "A magnetic field exerts a force on objects made of magnetic materials." Have students read the section and add to the brainstorming list.

Differentiated Instruction

Visually Impaired For students who cannot see the field lines in the illustrations and demonstrations, provide an opportunity to experiment with strong magnets. Make sure these students can feel the forces of attraction and repulsion between the magnets. [L1] **Kinesthetic**

Quick Demo

Magnetic Fields

Materials overhead projector, iron filings or an iron nail and file, petri dish or 2 overhead sheets, several different magnets

Estimated Time 15 minutes

Procedure Show magnetic fields on the overhead projector. Make iron filings by rubbing a metal file on an iron nail. Place the iron filings in a covered petri dish or between two overhead sheets. Place different magnets on top of the filings on the projector. Then show the fields between attracting and repelling poles, and how the fields change as you move the magnets slowly toward or away from each other. This demonstrates how field strength diminishes with distance. [L2]

ELL **LS** Visual-Spatial

Reading Check

Answer Like poles repel each other; unlike poles attract.

Content Background

Earth's magnetic poles do not perfectly align with Earth's geographic poles, the endpoints of the axis about which Earth rotates. Also, Earth's magnetic field is not fixed. The north magnetic pole has traveled about 10 km/year over the past century, and, many times in the past, magnetic north and south have switched places.

Unlike poles closest together

Like poles closest together

Figure 4 Two magnets can attract or repel each other, depending on which poles are closest together.

How Magnets Interact Two magnets can either attract or repel each other. Two north poles or two south poles of two magnets repel each other. However, north poles and south poles always attract each other. Like magnetic poles repel each other and unlike poles attract each other. When two magnets are brought close to each other, their magnetic fields combine to produce a new magnetic field. **Figure 4** shows the magnetic field that results when like poles and unlike poles of bar magnets are brought close to each other.

Reading Check How do magnetic poles interact with each other?

Magnetic Field Direction When a compass is brought near a bar magnet, the compass needle rotates. The compass needle is a small bar magnet with a north pole and a south pole. The force exerted on the compass needle by the magnetic field causes the needle to rotate. The compass needle rotates until it lines up with the magnetic field lines, as shown in **Figure 5**. The north pole of a compass points in the direction of the magnetic field. This direction is always away from a north magnetic pole and toward a south magnetic pole.

Figure 5 Compass needles placed around a bar magnet line up along magnetic field lines. The north poles of the compass needles are shaded red.

Visual Learning

Figure 4 What do you think happens to the magnetic force in the gaps between the lines? **The force is still there even though the lines don't show it.** [L2]

Cultural Diversity

Compasses Compasses were invented in China. By the ninth century A.D., the Chinese had discovered that magnetic north does not exactly coincide with geographic north. The compass was used for navigation at sea starting about 1,000 years ago (850–1050 A.D.). Before that they were used for a type of divination based on geographic features.

Earth's Magnetic Field A compass can help determine direction because the north pole of the compass needle points north. This is because Earth acts like a giant bar magnet and is surrounded by a magnetic field that extends into space. Just as with a bar magnet, the compass needle aligns with Earth's magnetic field lines, as shown in **Figure 6**.

Earth's Magnetic Poles The north pole of a magnet is defined as the end of the magnet that points toward the geographic north. Sometimes the north pole and south pole of a magnet are called the north-seeking pole and the south-seeking pole. Because opposite magnetic poles attract, the north pole of a compass is being attracted by a south magnetic pole. Earth is like a bar magnet with its south magnetic pole near its geographic north pole.

Currently, Earth's south magnetic pole is located in northern Canada, about 1,500 km from the geographic north pole. However, Earth's magnetic poles move slowly with time. Sometimes Earth's magnetic poles switch places so that Earth's south magnetic pole is in the southern hemisphere near the geographic south pole. Measurements of magnetism in rocks show that Earth's magnetic poles have changed places over 150 times in the past 70 million years.

No one is sure what produces Earth's magnetic field. Earth's inner core is made of a solid ball of iron and nickel, surrounded by a liquid layer of molten iron and nickel. According to one theory, circulation of the molten iron and nickel in Earth's outer core produces Earth's magnetic field.

Figure 6 A compass needle aligns with the magnetic field lines of Earth's magnetic field.
Predict Which way would a compass needle point if Earth's magnetic poles switched places?

SECTION 1 Magnetism 427

Fun Fact

Earth's magnetic field lines are not parallel to the surface. A carefully balanced magnetized needle can be used to measure the dip of the magnetic field, as well as its direction.

Curriculum Connection

History The compass was an important invention for navigation at sea. Have students research and write reports about some of the sea routes used before and after the invention of the compass. Most European exploration occurred after the adoption of the compass. Polynesian islanders and Vikings managed long sea voyages without the compass, depending on knowledge of the skies and the sea to find their way. **L2 P IS Kinesthetic**

Observing Magnetic Interference

Procedure

1. Clamp a **bar magnet** to a **ring stand**. Tie a **thread** around one end of a **paper clip** and stick the paper clip to one pole of the magnet.
2. Anchor the other end of the thread under a **book** on the table. Slowly pull the thread until the paper clip is suspended below the magnet but not touching it.
3. Without touching the paper clip, slip a piece of paper between the magnet and the paper clip. Does the paper clip fall?
4. Try other materials, such as **aluminum foil**, **fabric**, and a **butter knife**.

Analysis

1. Which materials caused the paper clip to fall? Why do you think these materials interfered with the magnetic field?
2. Which materials did not cause the paper clip to fall? Why do you think these materials did not interfere with the magnetic field?

Purpose Students observe that magnetic fields extend beyond the magnet and through barriers, and that some materials can affect the field. **L2 ELL**

IS Kinesthetic

Materials bar magnet, ring stand, 50 cm of thread, paper clip, tape, book, paper, aluminum foil, fabric, butter knife

Teaching Strategy Have students compare magnetic force to gravitational force. Remind students that gravitational force also acts through barriers.

Analysis

1. Some metals cause the paper clip to fall. These metals can be magnetized, so they affect the magnetic field.
2. Paper, glass, and plastic do not affect the field. The magnetic force is not affected by materials that cannot be magnetized.

Assessment

Process Have students examine the refrigerator door at home. Does it appear to be metal, or another material? Relate this to the lab. The plastic coating on some refrigerator doors does not interfere with the attraction between a magnet and the underlying metal. Use **Performance Assessment in the Science Classroom**, p. 89.

Caption Answer

Figure 6 toward the south magnetic pole in the southern hemisphere

Discussion

North Star What natural body has been used for centuries in the northern hemisphere to find the north-south direction? the star Polaris.

Magnets in Organisms Animals may perceive Earth's magnetic field by mechanical effects, where the magnetite is deflected like a compass needle. They may also sense field variations that cause electrical induction within the animal.

Applying Science

Answers

1. A magnet will attract about 65% of the total mass of the car. Other metals (such as aluminum and copper) are not magnetic and will not be attracted.
2. 525 kg
3. 9.75×10^9 kg

IDENTIFYING Misconceptions

Magnetic Metals Students may think that all metals are magnetic. See p. 422F for teaching strategies that address this misconception.

Magnets in Organisms Some organisms may use Earth's magnetic field to help them find their way around. Some species of birds, insects, and bacteria have been shown to contain small amounts of the mineral magnetite. Research how one species uses Earth's magnetic field, and report your findings to your class.

Applying Science

How can magnetic parts of a junk car be salvaged?

Every year over 10 million cars containing plastics, glass, rubber, and various metals are scrapped. Magnets are often used to help retrieve some of these materials from scrapped cars. The materials can then be reused, saving both natural resources and energy. Once the junk car has been fed into a shredder, large magnets can easily separate many of its metal parts from its nonmetal parts. How much of the car does a magnet actually help separate? Use your ability to interpret a circle graph to find out.

Identifying the Problem

The graph at the right shows the average percent by weight of the different materials in a car. Included in the magnetic metals are steel and iron. The nonmagnetic metals refer to aluminum, copper, lead, zinc, and magnesium. According to the graph, how much of the car can a magnet separate for recycling?

Solving the Problem

1. What percent of the car's weight will a magnet recover?
2. A certain scrapped car has a mass of 1,500 kg. What is the mass of the materials in this car that cannot be recovered using a magnet?
3. If the average mass of a scrapped car is 1,500 kg and 10 million cars are scrapped each year, what is the total mass of iron and steel that could be recovered from scrapped cars each year?

LAB DEMONSTRATION

Purpose to show how a hard blow can magnetize a steel rod aligned with Earth's magnetic field

Materials compass, steel rod, hammer, paper clips, protractor

Preparation Use the compass to mark a line on the ground running north-south.

Procedure Position the rod along the north-south line as shown. Sharply rap the south end of the rod with a hammer.

Expected Outcome The rod becomes magnetized and will pick up a few clips. Repeat if needed, as this effect depends on hitting the rod just right.

Assessment

What happened to the magnetic domains in the steel rod when it was struck with the hammer? **They were jolted and could realign. Enough of the magnetic domains realigned along Earth's field lines to make a magnet.** L2

Magnetic Domains—A Model for Magnetism In iron, cobalt, nickel, and some other magnetic materials, the magnetic field created by each atom exerts a force on the other nearby atoms. Because of these forces, large groups of atoms align their magnetic poles so that almost all like poles point in the same direction. The groups of atoms with aligned magnetic poles are called **magnetic domains**. Each domain contains an enormous number of atoms, yet the domains are too small to be seen with the unaided eye. Because the magnetic poles of the individual atoms in a domain are aligned, the domain itself behaves like a magnet with a north pole and a south pole.

Lining Up Domains An iron nail contains an enormous number of these magnetic domains, so why doesn't the nail behave like a magnet? Even though each domain behaves like a magnet, the poles of the domains are arranged randomly and point in different directions, as shown in **Figure 7**. As a result, the magnetic fields from all the domains cancel each other out.

If you place a magnet against the same nail, the atoms in the domains orient themselves in the direction of the nearby magnetic field, as shown on the right in **Figure 7**. The like poles of the domains point in the same direction and no longer cancel each other out. The nail itself now acts as a magnet. However, when the external magnetic field is removed, the constant motion and vibration of the atoms bump the magnetic domains out of their alignment. The magnetic domains in the nail return to a random arrangement. For this reason, the nail is only a temporary magnet. Paper clips and other objects containing iron also can become temporary magnets.

Figure 7 Magnetic materials contain magnetic domains.

A normal iron nail is made up of microscopic domains that are arranged randomly.

The domains will align themselves along the magnetic field lines of a nearby magnet.

Making Your Own Compass

Procedure

WARNING: Use care when handling sharp objects.

1. Cut off the bottom of a **plastic foam cup** to make a polystyrene disk.
2. Magnetize a **sewing needle** by continuously stroking the needle in the same direction with a magnet for 1 min.
3. **Tape** the needle to the center of the foam disk.
4. Fill a **plate** with **water** and float the disk, needle-side up, in the water.
5. Bring the magnet close to the foam disk.

Analysis

1. How did the needle and disk move when you placed them in the water? Explain.
2. How did the needle and disk move when the magnet was brought near? Explain.

Use an Analogy

Rope Pulling Lining up magnetic domains is like getting a group of people to pull together on one end of a rope. If each person pulls the rope in a different direction, the pulls cancel each other and nothing happens. If they all pull together in one direction, the individual forces add together.

Purpose Students will make a compass. **L2** **LS** **Kinesthetic**

Materials plastic foam cup, magnet, sewing needle, tape, plate, water

Teaching Strategy Remind students that the sewing needle contains, or is made of, iron.

Safety Precautions Caution students to handle the needle with care.

Analysis

1. The needle aligned with Earth's magnetic field lines.
2. The needle swung around to point toward the magnet. The magnet's field is stronger than Earth's at that distance, so the needle aligns with the magnet's magnetic field.

Assessment

Oral What causes the needle to become magnetic when you stroke it with the magnet? **The magnet rearranges the domains in the needle so that they line up and make the needle magnetic.** Use **Performance Assessment in the Science Classroom**, p. 89.

Teacher FYI

Rock Minerals Iron minerals in some rocks (such as basalt) align themselves with Earth's magnetic field if the rock forms under the right conditions. This provides a record of Earth's changing magnetic field, which is studied by geologists and those hoping to determine Earth's past climates.

Post Reading

Cooperative Learning Project

Have students work in groups to research an application of magnetism. For example, students might investigate MRI machines or magnetic recording. Encourage students to develop a ten-minute oral presentation augmented by a visual aide.

3 Assess

DAILY INTERVENTION

Check for Understanding

Visual-Spatial Have students use Figure 4 to make illustrations of the magnetic field of two bar magnets with like poles near each other and with unlike poles near each other. Have students clearly label the poles on the illustrations. [L2]

Reteach

Magnetizing a Nail Hang a nail, by the flat head, from the end of a bar magnet. Next, place the nail and a compass on the overhead to show that the nail has N and S poles. [AS] **Visual-Spatial** [L2]

Assessment

Performance Ask students to use a compass to map the magnetic field of a large horseshoe magnet. Use **Performance Assessment in the Science Classroom**, p. 97. [L2]

Figure 8 Each piece of a broken magnet still has a north and a south pole.

Permanent Magnets A permanent magnet can be made by placing a magnetic material, such as iron, in a strong magnetic field. The strong magnetic field causes the magnetic domains in the material to line up. The magnetic fields of these aligned domains combine and create a strong magnetic field inside the material. This field prevents the constant motion of the atoms from bumping the domains out of alignment. The material is then a permanent magnet.

Even permanent magnets can lose their magnetic behavior if they are heated. Heating causes atoms in a magnet to move faster. If a permanent magnet is heated enough, its atoms may be moving fast enough to jostle the domains out of alignment. Then the permanent magnet loses its magnetic field and is no longer a magnet.

Can a pole be isolated? What happens when a magnet is broken in two? Can one piece be a north pole and one piece be a south pole? Look at the domain model of the broken magnet in **Figure 8**. Recall that even individual atoms of magnetic materials act as tiny magnets. Because every magnet is made of many aligned smaller magnets, even the smallest pieces have both a north pole and a south pole.

section 1 review

Summary

Magnets

- A magnet is surrounded by a magnetic field that exerts a force on magnetic materials.
- A magnet has a north pole and a south pole.
- Like magnetic poles repel and unlike poles attract.

Magnetic Materials

- Iron, cobalt, and nickel are magnetic elements because their atoms behave like magnets.
- Magnetic domains are regions in a material that contain an enormous number of atoms with their magnetic poles aligned.
- A magnetic field causes domains to align. In a temporary magnet, the domains return to a random alignment when the field is removed.
- In a permanent magnet, a strong magnetic field aligns domains, and they remain aligned when the field is removed.

Self Check

1. **Describe** what happens when you move two unlike magnetic poles closer together. Draw a diagram to illustrate your answer.
2. **Describe** how a compass needle moves when it is placed in a magnetic field.
3. **Explain** why only certain materials are magnetic.
4. **Predict** how the properties of a bar magnet would change if it were broken in half.
5. **Explain** how heating a bar magnet would change its magnetic field.
6. **Think Critically** Use the magnetic domain model to explain why a magnet sticks to a refrigerator door.

Applying Math

7. **Calculate Number of Domains** The magnetic domains in a magnet have an average volume of 0.0001 mm^3 . If the magnet has dimensions of 50 mm by 10 mm by 4 mm, how many domains does the magnet contain?

section 1 review

1. The poles attract one another.
2. It aligns itself along the field lines.
3. The atoms of magnetic materials are themselves individual magnets. They form magnetic domains containing large numbers of atoms. Each domain is a magnet. A magnet brought nearby causes domains to align so they are attracted to the nearest pole of the magnet.
4. Each piece still would contain large numbers of domains and have a north pole and a south pole. Because each piece contains few domains, the magnetic field of each piece would be weaker.
5. When the magnet is heated, the atoms in the magnet move faster. If the atoms are moving fast enough, collisions with other atoms may cause atoms in domains to become unaligned. This would reduce the magnetic field.
6. If the metal in the door contains a magnetic material, the magnetic domains align when the magnet is brought close so the opposite poles of the domains attract the closest pole of the magnet.
7. $(50 \text{ mm})(10 \text{ mm})(4 \text{ mm}) / 0.0001 \text{ mm}^3 = 2.0 \times 10^7$

Electricity and Magnetism

Reading Guide

What You'll Learn

- **Describe** the magnetic field produced by an electric current.
- **Explain** how an electromagnet produces a magnetic field.
- **Describe** how electromagnets are used.
- **Explain** how an electric motor operates.

Why It's Important

Electric motors contained in many of the devices you use every day operate because electric currents produce magnetic fields.

FCAT Vocabulary

Review Vocabulary

electric current: the flow of electric charges in a wire or any conductor

New Vocabulary

- ★ **electromagnet**
- solenoid
- galvanometer
- electric motor

Electric Current and Magnetism

In 1820, Hans Christian Oersted, a Danish physics teacher, found that electricity and magnetism are related. While doing a demonstration involving electric current, he happened to have a compass near an electric circuit. He noticed that the flow of the electric current affected the direction the compass needle pointed. Oersted hypothesized that the electric current must have produced a magnetic field around the wire, and that the direction of the field changed with the direction of the current.

Moving Charges and Magnetic Fields Oersted's hypothesis that an electric current creates a magnetic field was correct.

Moving charges, such as those in an electric current, produce magnetic fields. Around a current-carrying wire the magnetic field lines form circles, as shown in **Figure 9**. The direction of the magnetic field around the wire reverses when the direction of the current in the wire reverses. As the current in the wire increases, the strength of the magnetic field increases. As the distance from the wire increases, the strength of the magnetic field decreases.

Figure 9 When electric current flows through a wire, a magnetic field forms around the wire. The direction of the magnetic field depends on the direction of the current in the wire.

Fun Fact

The source of Earth's magnetic field is still not well understood. One hypothesis is that convection currents of molten rock deep in Earth's core generate electric currents, which in turn generate a magnetic field, just like the current in a wire.

Discussion

Crane's Magnet Explain that a crane can have a grabbing end to pick up an object, or it can use an electromagnet. Compare the two cranes. Possible responses: the electromagnet will only work on certain types of metals, while the mechanical crane can lift anything it can grab. The strength of the mechanical crane depends on the materials it is made from and how they are attached; the strength of the electromagnet crane depends on these factors plus the number of turns in the coil and the strength of the current running through it. **L2**

Logical-Mathematical

Caption Answer

Figure 10B The direction of the magnetic field would be reversed.

Reading Strategy

Paraphrase Ask students to paraphrase sections of the text. Be sure students know that paraphrasing involves putting text material into their own words. The paraphrase, a condensed version of the text, is shorter than the original section. Have students paraphrase the text orally to a partner or in writing.

Electromagnets

The magnetic field that surrounds a current-carrying wire can be made much stronger in an electromagnet. An **electromagnet** is a temporary magnet made by wrapping a wire coil carrying a current around an iron core. When a current flows through a wire loop, such as the one shown in **Figure 10A**, the magnetic field inside the loop is stronger than the field around a straight wire. A single wire wrapped into a cylindrical wire coil is called a **solenoid**. The magnetic field inside a solenoid is stronger than the field in a single loop. The magnetic field around each loop in the solenoid combines to form the field shown in **Figure 10B**.

If the solenoid is wrapped around an iron core, an electromagnet is formed, as shown in **Figure 10C**. The solenoid's magnetic field magnetizes the iron core. As a result, the field inside the solenoid with the iron core can be more than 1,000 times greater than the field inside the solenoid without the iron core.

Properties of Electromagnets Electromagnets are temporary magnets because a magnetic field is present only when current is flowing in the solenoid. The strength of the magnetic field can be increased by adding more turns of wire to the solenoid or by increasing the current passing through the wire.

An electromagnet behaves like any other magnet when current flows through the solenoid. One end of the electromagnet is a north pole and the other end is a south pole. If it is placed in a magnetic field, an electromagnet will align itself along the magnetic field lines, just as a compass needle will. An electromagnet also will attract magnetic materials and be attracted or repelled by other magnets. What makes an electromagnet so useful is that its magnetic properties can be controlled by changing the electric current flowing through the solenoid.

When current flows in an electromagnet and it moves toward or away from another magnet, electric energy is converted into mechanical energy to do work. Electromagnets do work in various devices, such as stereo speakers and electric motors.

Figure 10 An electromagnet is made from a current-carrying wire.

A The magnetic fields around different parts of the wire loop combine to form the field inside the loop.

B When many loops of current-carrying wire are formed into a solenoid, the magnetic field is increased inside the solenoid. The solenoid has a north pole and a south pole.

Predict how the field would change if the current reversed direction.

C A solenoid wrapped around an iron core forms an electromagnet.

Differentiated Instruction

English-Language Learners For students who have difficulty following diagrams and complex descriptions, focus on the basic definitions—for example, that a motor converts electricity into motion. Provide a chance for students to observe, handle, and take apart a simple motor or generator. **L1** **Kinesthetic**

Teacher FYI

Electrons Each electron in an atom acts like a tiny electromagnet—the electron orbiting the nucleus is a loop of electric current, just like electrons moving in a wire. An electron also has “spin,”—a quantum physics characteristic that contributes to the magnetic field generated by the electron.

Figure 11 The electromagnet in a speaker converts electrical energy into mechanical energy to produce sound.

Explain why a speaker needs a permanent magnet to produce sound.

Using Electromagnets to Make Sound How does musical information stored on a CD become sound you can hear? The sound is produced by a loudspeaker that contains an electromagnet connected to a flexible speaker cone that is usually made from paper, plastic, or metal. The electromagnet changes electrical energy to mechanical energy that vibrates the speaker cone to produce sound, as shown on **Figure 11**.

Reading Check How does a stereo speaker use an electromagnet to produce sound?

When you listen to a CD, the CD player produces a voltage that changes according to the musical information on the CD. This varying voltage produces a varying electric current in the electromagnet connected to the speaker cone. Both the amount and the direction of the electric current change, depending on the information on the CD. The varying electric current causes both the strength and the direction of the magnetic field in the electromagnet to change. The electromagnet is surrounded by a permanent, fixed magnet. The changing direction of the magnetic field in the electromagnet causes the electromagnet to be attracted to or repelled by the permanent magnet. This makes the electromagnet move back and forth, causing the speaker cone to vibrate and reproduce the sound that was recorded on the CD.

Curriculum Connection

History Have students find out how Alexander Graham Bell used an electromagnet in the first telephone and present their findings to the class.

L2 **IS** **Linguistic**

Quick Demo Electromagnets

Materials large nail, battery, battery holder, wire

Estimated Time 15 minutes

Procedure Make an electromagnet by connecting a battery to a wire coiled 20 times around a large nail. Demonstrate that the nail picks up no paper clips before the wire is connected and several when it is connected. When the wire again is disconnected, the paper clips should fall. However, the nail will still be slightly magnetized and may pick up one or two paper clips after the current is turned off.

WARNING: The wire will heat up if it is left connected, so disconnect the battery as soon as you are done.

L2 **IS** **Visual-Spatial**

Caption Answer

Figure 11 The permanent magnet attracts and repels the electromagnet, causing the speaker cone to vibrate and produce sound.

Visual Learning

Figure 11 Have students analyze the diagram of the speaker. Review step by step the process in which electrical energy is converted to sound energy. Make sure students understand that the changing electrical signal causes a changing magnetic field in the electromagnet, and that the interaction of that magnetic field with the magnetic field of the permanent magnet causes the electromagnet to move.

Reading Check

Answer The electromagnet changes electrical energy to mechanical energy that vibrates parts of the speaker to produce sound.

Inquiry Lab

Observing an Electric Motor

Purpose To construct and observe a simple electric motor.

Possible Materials pliable copper wire, stiff bare copper wire, D-cell battery, D-cell battery holder, wire cutters or pliers, permanent magnet, tape

Estimated Time one class period

Teaching Strategies

- Students can brainstorm about how they will construct a simple electric motor by creating a coil of wire suspended above a permanent magnet.
- The battery can be used to create a flow of current in the wire coil.
- Students can observe the principles of an electric motor.
- Allow students to explore other questions that arise.

For additional inquiry activities, see *Science Inquiry Labs*.

✓ Reading Check

Answer When current flows in the solenoid, like poles of the electromagnet are repelled by and attracted to the poles of the permanent magnet. This causes the electromagnet to rotate.

When a current flows into the solenoid, like poles of the electromagnet are repelled by and attracted to the poles of the permanent magnet. This causes the electromagnet to rotate.

Figure 12 An electromagnet can be made to rotate in a magnetic field.

The magnetic forces on the electromagnet cause it to rotate until it is aligned along the field lines of the permanent magnet.

Making an Electromagnet Rotate The forces exerted on an electromagnet by another magnet can be used to make the electromagnet rotate. **Figure 12** shows an electromagnet suspended between the poles of a permanent magnet. The poles of the electromagnet are repelled by the like poles and attracted by the unlike poles of the permanent magnet. When the electromagnet is in the position shown on the left side of **Figure 12**, there is a downward force on the left side and an upward force on the right side of the electromagnet forces. These forces cause the electromagnet to rotate as shown.

✓ Reading Check

How can a permanent magnet cause an electromagnet to rotate?

The electromagnet continues to rotate until its poles are next to the opposite poles of the permanent magnet, as shown on the right side of **Figure 12**. In this position, the forces on the north and south poles of the electromagnet are in opposite directions. The net force on the electromagnet is now zero, and the electromagnet stops rotating.

One way to change the forces that make the electromagnet rotate is to change the current in the electromagnet. Increasing the current increases the strength of the forces that the two magnets exert on each other.

Galvanometers You've probably noticed the gauges in the dashboard of a car. One gauge shows the amount of gasoline left in the tank, and another shows the engine temperature. How does a change in the amount of gasoline in a tank or the water temperature in the engine make a needle move in a gauge on the dashboard? These gauges are **galvanometers**, which are devices that use an electromagnet to measure electric current.

Cultural Diversity

China The first dial and pointer devices were made in China, using compass needles. Modern dials and pointers, including galvanometers, descend from these early Chinese devices.

Figure 13 The rotation of the needle in a galvanometer depends on the amount of current flowing in the electromagnet. The current flowing into the galvanometer in a car's fuel gauge changes as the amount of fuel changes.

Using Galvanometers An example of a galvanometer is shown in **Figure 13**. In a galvanometer, the electromagnet is connected to a small spring. The electromagnet rotates until the force exerted by the spring is balanced by the magnetic forces on the electromagnet. Changing the current in the electromagnet causes the needle to rotate to different positions on the scale.

For example, a car's fuel gauge uses a galvanometer. A float in the fuel tank is attached to a sensor that sends a current to the fuel-gauge galvanometer. As the level of the float in the tank changes, the current sent by the sensor changes. The changing current in the galvanometer causes the needle to rotate by different amounts. The gauge is calibrated so that the current sent when the tank is full causes the needle to rotate to the full mark on the scale.

Electric Motors

On sizzling summer days, do you ever use an electric fan to keep cool? A fan uses an **electric motor**, which is a device that changes electrical energy into mechanical energy. The motor in a fan turns the fan blades, moving air past your skin to make you feel cooler.

Electric motors are used in all types of industry, agriculture, and transportation, including airplanes and automobiles. If you were to look carefully, you probably could find electric motors in every room of your home. Almost every appliance in which something moves contains an electric motor. Electric motors are used in devices such as VCRs, CD players, and computers, and appliances such as those shown in **Figure 14**.

Figure 14 All the devices shown here contain electric motors.

List three additional devices that contain electric motors.

Use Science Words

Word Origin Have students use a dictionary to find the origin of the word *motor*. It is derived from the Latin word for move. **L2** **IS** **Linguistic**

Activity

Hobby Motors Bring a set of direct current hobby motors to class. Have students take them apart and identify the different parts. **L2**

Discussion

Galvanometers Have students describe all the dials with pointers they can find in their homes, school, cars, etc. Which ones are galvanometers? **Possible answer:** Older voltmeters and ammeters contain galvanometers. Some gauges in a car are galvanometers. A clock is an example of a motorized measuring device that is not a galvanometer. **L3** **IS** **Logical-Mathematical**

Caption Answer

Figure 14 Answers will vary.

Curriculum Connection

History Have students research the history of the development of electric motors. Have them present their findings in the form of a newspaper article. The first commercially useful electric motor was a reversible DC electrical generator built in the early 1870s by Zénobe-Théophile Gramme. The first practical AC motor was built in 1888 by Nikola Tesla. **L2** **P** **IS** **Linguistic**

Use an Analogy

Waterwheel An electric motor is like a waterwheel. A force (running water, magnetism) applied to a wheel (paddle of wheel, end of magnet) turns an axle. In either case, things can be attached to the axle to use the mechanical energy produced.

Make a Model

Simple Electric Motors Have students use **Figure 15** as a guide to make models of simple electric motors. **L3** **KS** **Kinesthetic**

Step 1 When a current flows in the coil, the magnetic forces between the permanent magnet and the coil cause the coil to rotate.

Step 2 In this position, the brushes are not in contact with the commutator and no current flows in the coil. The inertia of the coil keeps it rotating.

Step 3 The commutator reverses the direction of the current in the coil. This flips the north and south poles of the magnetic field around the coil.

Step 4 The coil rotates until its poles are opposite the poles of the permanent magnet. The commutator reverses the current, and the coil keeps rotating.

Figure 15 In a simple electric motor, a coil rotates between the poles of a permanent magnet. To keep the coil rotating, the current must change direction twice during each rotation.

A Simple Electric Motor A diagram of the simplest type of electric motor is shown in **Figure 15**. The main parts of a simple electric motor include a wire coil, a permanent magnet, and a source of electric current, such as a battery. The battery produces the current that makes the coil an electromagnet. A simple electric motor also includes components called brushes and a commutator. The brushes are conducting pads connected to the battery. The brushes make contact with the commutator, which is a conducting metal ring that is split. Each half of the commutator is connected to one end of the coil so that the commutator rotates with the coil. The brushes and the commutator form a closed electric circuit between the battery and the coil.

Differentiated Instruction

Challenge Have students find out more about how the commutator in an electric motor works. Have students prepare an oral presentation to present to the class. The commutator rotates with the electromagnet and alternately contacts the positive and

negative terminals of the power source. The reversing current causes the poles of the rotating electromagnet to switch and rotate toward the opposite pole of the permanent magnet.

L3 **KS** **Logical-Mathematical**

Making the Motor Spin When current flows in the coil, the forces between the coil and the permanent magnet cause the coil to rotate, as shown in step 1 of **Figure 15**. The coil continues to rotate until it reaches the position shown in step 2. Then, the brushes no longer make contact with the commutator, and no current flows in the coil. As a result, there are no magnetic forces exerted on the coil. However, the inertia of the coil causes it to continue rotating.

In step 3, the coil has rotated so that the brushes again are in contact with the commutator. However, the halves of the commutator that are in contact with the positive and negative battery terminals have switched. This causes the current in the commutator to reverse direction. Now the top of the electromagnet is a north magnetic pole and the bottom is a south pole. These poles are repelled by the nearby like poles of the permanent magnet, and the magnet continues to rotate.

In step 4, the coil rotates until its poles are next to the opposite poles of the permanent magnet. Then the commutator again reverses the direction of the current, enabling the coil to keep rotating. In this way, the coil is kept rotating as long as the battery remains connected to the commutator.

section 2 review

Summary

Electric Current and Magnetic Fields

- A magnetic field surrounds a moving electric charge.
- The strength of the magnetic field surrounding a current-carrying wire depends on the amount of current.

Electromagnets

- An electromagnet is a temporary magnet consisting of a current-carrying wire wrapped around an iron core.
- The magnetic properties of an electromagnet can be controlled by changing the current in the coil.
- A galvanometer uses an electromagnet to measure electric current.

Electric Motors

- In a simple electric motor, an electromagnet rotates between the poles of a permanent magnet.

Self Check

1. **Explain** why, if the same current flows in a wire coil and a single wire loop, the magnetic field inside the coil is stronger than the field inside the loop.
2. **Describe** two ways you could change the strength of the magnetic field produced by an electromagnet.
3. **Predict** how the magnetic field produced by an electromagnet would change if the iron core were replaced by an aluminum core.
4. **Explain** why it is necessary to continually reverse the direction of current flow in the coil of an electric motor.
5. **Think Critically** A bar magnet is repelled when an electromagnet is brought close to it. Describe how the bar magnet would have moved if the current in the electromagnet had been reversed.

Applying Math

6. **Use a Ratio** The magnetic field strength around a wire at a distance of 1 cm is twice as large as at a distance of 2 cm. How does the field strength at 0.5 cm compare to the field strength at 1 cm?

More Section Review fl.gpscience.com

SECTION 2 Electricity and Magnetism 437

section 2 review

1. The magnetic field around each bit of wire has the same strength, but when the wire is looped, the fields combine, making a stronger field.
2. by varying the electric current passing through it or by changing the number of loops
3. The magnetic field would be weaker because aluminum is not a magnetic material. The only magnetic field would be that created by the looped wire.
4. When an end of the coil moves past a pole of the permanent magnet, reversing the current causes the end of the coil to be attracted to the other pole of the permanent magnet. Repeating this process keeps the coil continually rotating in the same direction.
5. The bar magnet would have been attracted to the electromagnet because the pole would have been opposite to what it was.
6. It would be twice as large as the strength at 1 cm and four times the strength at 2 cm.

MA.B.1.4.1

Assessment

Oral Demonstrate the different speeds on a fan or mixer. Ask students how they think the speed is varied. To make the appliance rotate faster, the amount of current passing through the coil of the electric motor is increased. To slow down the appliance, the amount of current is decreased. Reading Guide

What You'll Learn

- **Define** electromagnetic induction.
- **Describe** how a generator produces an electric current.
- **Distinguish** between alternating current and direct current.
- **Explain** how a transformer can change the voltage of an alternating current.

Why It's Important

Electromagnetic induction enables power plants to generate the electric current an appliance uses when you plug it into an electric outlet.

Review Vocabulary

voltage difference: a measure of the electrical energy provided by charges as they flow in a circuit

New Vocabulary

- electromagnetic induction
- generator
- turbine
- direct current (DC)
- alternating current (AC)
- transformer

From Mechanical to Electrical Energy

Working independently in 1831, Michael Faraday in Great Britain and Joseph Henry in the United States both found that moving a loop of wire through a magnetic field causes an electric current to flow in the wire. They also found that moving a magnet through a loop of wire produces a current. In both cases, the mechanical energy associated with the motion of the wire loop or the magnet is converted into electrical energy associated with the current in the wire. The magnet and wire loop must be moving relative to each other for an electric current to be produced. This causes the magnetic field inside the loop to change with time. In addition, if the current in a wire changes with time, the changing magnetic field around the wire can also induce a current in a nearby coil. The generation of a current by a changing magnetic field is **electromagnetic induction**.

Generators Most of the electrical energy you use every day is provided by generators. A **generator** uses electromagnetic induction to transform mechanical energy into electrical energy. **Figure 16** shows one way a generator converts mechanical energy to electrical energy. The mechanical energy is provided by turning the handle on the generator.

An example of a simple generator is shown in **Figure 17**. In this type of generator, a current is produced in the coil as the coil rotates between the poles of a permanent magnet.

Figure 16 The coil in a generator is rotated by an outside source of mechanical energy. Here the student supplies the mechanical energy that is converted into electrical energy by the generator.

✓ Reading Check

Answer *twice*

Switching Direction As the generator's wire coil rotates through the magnetic field of the permanent magnet, current flows through the coil. After the wire coil makes one-half of a revolution, the ends of the coil are moving past the opposite poles of the permanent magnet. This causes the current to change direction. In a generator, as the coil keeps rotating, the current that is produced periodically changes direction. The direction of the current in the coil changes twice with each revolution, as **Figure 17** shows. The frequency with which the current changes direction can be controlled by regulating the rotation rate of the generator. In the United States, current is produced by generators that rotate 60 times a second, or 3,600 revolutions per minute.

✓ **Reading Check** For each revolution of the coil, how many times does the current change direction?

The Electromagnetic Force There is a relationship between electricity and magnetism. A changing magnetic field can cause electric charges to move in a wire. Also, a moving electric charge produces a magnetic field. The atoms of magnetic materials, such as iron, are magnets because of the motion of electric charges in the atoms. As a result, the magnetic field around a permanent magnet is due to electric charges that are in motion.

This connection occurs because the electric force and the magnetic force are two different aspects of the same force. This force is the electromagnetic force and is one of the fundamental forces in nature. An electromagnetic force exists between all objects that have electric charge. Just like the magnetic and the electric force, the electromagnetic force can be attractive or repulsive.

Figure 17 The current in the coil changes direction each time the ends of the coil move past the poles of the permanent magnet.

Explain how the frequency of the changing current can be controlled.

IDENTIFYING Misconceptions

Magnetic Fields Some students may think that a magnetic field alone is enough to produce a current. Emphasize that the magnetic field must be changing to induce a current in the wire coil. A stationary magnet and loop will not generate a current.

Use Science Words

Word Meaning The expression *electromagnetic induction* is related to the word *induce*. Have students find the common meaning of induce and use it in a sentence. *Induce* means to move to a course of action, to cause; sample sentence: The king induced his knights to follow his lead. **L2** **IS** Linguistic

Caption Answer

Figure 17 by regulating the rotation rate of the generator

Science Journal

History of Technology A turbine transforms straight-line motion into rotational motion. One of the oldest means of transforming motion this way is the waterwheel. Have students write paragraphs in their Science Journals comparing the design of a waterwheel with that of a hydroelectric turbine. **L2** **IS** Linguistic

Discussion

Number of Power Plants Why is electricity usually generated at a few large plants, rather than many small ones? **Possible answer:** Generating plants are often located near rivers, dams, or other energy sources. Multiple small plants would require redundant resources and would be more expensive to build. **L3** **IS** **Logical-Mathematical**

INTEGRATE Career

Power-Plant Operator These operators control and monitor the boilers, turbines, generators, and other equipment at power generating plants. Power-plant operators may use computers for many tasks including generating reports of daily operations or unusual incidents.

Research Have students research the future employment outlook for this career.

Quick Demo Generating Current

Materials hand-operated generator, wire, bulb socket, lightbulb

Estimated Time ten minutes

Procedure Attach wire leads to the hand generator and to the bulb socket containing a lightbulb. Slowly turn the hand generator to light the bulb. Additional lightbulbs can be added in parallel or in series. Vary the speed that you turn the hand generator and show students the effect on the brightness of the lights.

Figure 18 Each of these generators at Hoover Dam can produce over 100,000 kW of electric power. In these generators, a rotating magnet induces an electric current in a stationary wire coil.

INTEGRATE Career

Power-Plant Operator Many daily activities require electricity. Power-plant operators control the machinery that generates electricity. Operators must have a high school diploma. College-level courses may be helpful. Research to find employers in your area that hire power plant operators.

Generating Electricity for Your Home You probably do not have a generator in your home that supplies the electrical energy you use at home. This electrical energy comes from a power plant with huge generators like the one in **Figure 18**. The coils in these generators have many coils of wire wrapped around huge iron cores. The rotating magnets are connected to a **turbine**, which is a large wheel that rotates when pushed by water, wind, or steam.

Some power plants first produce thermal energy by burning fossil fuels or using the heat produced by nuclear reactions. This thermal energy is used to heat water and produce steam. Thermal energy is then converted to mechanical energy as the steam pushes the turbine blades. The generator then changes the mechanical energy of the rotating turbine into the electrical energy you use. In some areas, fields of windmills, such as those in **Figure 18**, can be used to capture the mechanical energy in wind to turn generators. Other power plants use the mechanical energy in falling water to rotate the turbines. Both generators and electric motors use magnets to produce energy conversions between electrical and mechanical energy. **Figure 20** summarizes the differences between electric motors and generators.

Figure 19 The propeller on each of these windmills is connected to an electric generator. The rotating propeller rotates a coil or a permanent magnet.

Curriculum Connection

Geography Solar power can be used to generate electricity. A very large array is needed to generate enough electricity for a city, and only very sunny sites will do. Ask students to research and report on areas in the United States that are suitable for such solar generators. **Large solar arrays have been proposed for the Southwest's deserts, particularly those in California.** **L2** **P** **IS** **Linguistic**

Visual Learning

Figure 19 In the 1920s and 1930s, before rural areas had access to electricity from power plants, people sometimes used small windmills to run water pumps or household generators. The windmills shown are much larger, of course. Windmills on “wind farms,” such as the one shown in the figure, can be as big as 50 m in diameter and stand several building stories high.

Figure 20

Electric motors power many everyday machines, from CD players to vacuum cleaners. Generators produce the electricity these motors need to run. Both motors and generators use electromagnets, but in different ways. The table below compares motors and generators.

	Electric Motor	Generator
What does it do?	Changes electricity into movement 	Changes movement into electricity 
What makes its electromagnetic coil rotate?	Attractive and repulsive forces between the coil and the permanent magnet 	An outside source of mechanical energy 
What is the source of the current that flows in its coil?	An outside power source 	Electromagnetic induction from moving the coil through the field of the permanent magnet 
How often does the current in the coil change direction?	Twice during each rotation of the coil	Twice during each rotation of the coil

Visualizing Motors and Generators

Have students examine the pictures and read the captions. Then ask the following questions.

In what way is an electric motor the opposite of a generator? In what way is it the same? **Opposite:** A motor changes electricity into movement, while a generator changes movement into electricity. **Same:** The current in the coil changes direction twice during each rotation of the coil.

What kind of movement produces the electricity in hydroelectric generators? **moving water** In windmills? **moving air** In a bicycle generator? **moving bicycle wheel**

Activity

Hand-Cranked Power Have small groups of students research power supplies used for camping or emergency situations that produce electricity from a hand-cranked generator. These devices include flashlights, lanterns, and radios. Have students make oral presentations about how these devices work and in what situations they would be most useful.

L2 COOP LEARN

LS Logical-Mathematical

Differentiated Instruction

Challenge Students could research the differences between AC and DC generators and make labeled posters illustrating the differences between these two ways that electricity is transmitted. **L3** **LS** Visual-Spatial

Teacher FYI

Current Disagreement Thomas Edison advocated the use of DC to transmit electric current. One of his workers, Nikola Tesla, argued that an AC current would be better. Edison and Tesla parted ways, and Tesla went to work for Edison's competitor, the Westinghouse Company. Today, electric current in the United States is distributed using AC.

Virtual Labs

 **Generators** How does a generator work?

Reading Strategy

Cause and Effect Have students set up a chart with the headings *Cause* and *Effect*. Under *Effect*, have students list the following: a generator transforms mechanical energy into electrical energy, a radio plays music, and a transformer increases voltage. Have students use the text to find the cause for each effect.

Scienceonline

Topic: Transformers

Visit fl.gpscience.com for links to information about how transformers transmit electric current.

Activity In England, voltage from an outlet is greater than required for U.S. appliances. Using information found at these links, diagram a transformer that would allow a U.S. appliance to operate in England.

Figure 21 Some devices, such as this radio, can use either direct or alternating current. Electronic components in these devices change alternating current from an electric outlet to direct current.

Direct and Alternating Currents

Modern society relies heavily on electricity. Just how much you rely on electricity becomes obvious during a power outage. Out of habit, you might walk into a room and flip on the light switch. You might try to turn on a radio or television or check the clock to see what time it is. Because power outages sometimes occur, some electrical devices, such as the radio in **Figure 21**, use batteries as a backup source of electrical energy. However, the current produced by a battery is different from the current produced by an electric generator.

A battery produces a direct current. **Direct current** (DC) flows only in one direction through a wire. When you plug your CD player or any other appliance into a wall outlet, you are using alternating current. **Alternating current** (AC) reverses the direction of the current in a regular pattern. In North America, generators produce alternating current at a frequency of 60 cycles per second, or 60 Hz. The electric current produced by a generator changes direction twice during each cycle, or each rotation, of the coil. This means that a 60-Hz alternating current changes direction 120 times each second.

Electronic devices that use batteries as a backup energy source usually require direct current to operate. When the device is plugged into a wall outlet, electronic components inside the device convert the alternating current to direct current and also reduce the voltage of the alternating current.

Transmitting Electrical Energy

The alternating current produced by an electric power plant carries electrical energy that is transmitted along electric transmission lines. However, when electrical energy is transmitted along power lines, some of the electrical energy is converted into heat because of the electrical resistance of the wires. The heat produced in the power lines warms the wires and the surrounding air and can't be used to power electrical devices. Also, the electrical resistance and heat production increase as the wires get longer. As a result, large amounts of heat can be produced when electrical energy is transmitted over long distances.

One way to reduce the heat produced in a power line is to transmit the electrical energy at high voltages, typically around 150,000 V. However, electrical energy at such high voltage cannot enter your home safely, nor can it be used in home appliances. Instead, a transformer is used to decrease the voltage.

Science Journal

Nikola Tesla Tell students that the inventor Nikola Tesla brought alternating current into wide usage. Have students find out where he was from, when he lived, and how he spread the use of alternating current, and write their findings in their Science Journals. Tesla lived from 1856 to 1943. He was

Serbian, born in Croatia. He convinced businessman and inventor George Westinghouse that alternating current could be transported more efficiently than direct current. Westinghouse's company, General Electric, was able to develop commercial AC systems that soon were widely adopted. **L2** **LS** **Linguistic**

Transformers

A **transformer** is a device that increases or decreases the voltage of an alternating current. A transformer is made of a primary coil and a secondary coil. These wire coils are wrapped around the same iron core, as shown in **Figure 22**. As an alternating current passes through the primary coil, the coil's magnetic field magnetizes the iron core. The magnetic field in the primary coil changes direction as the current in the primary coil changes direction. This produces a magnetic field in the iron core that changes direction at the same frequency. The changing magnetic field in the iron core then induces an alternating current with the same frequency in the secondary coil.

The voltage in the primary coil is the input voltage, and the voltage in the secondary coil is the output voltage. The output voltage divided by the input voltage equals the number of turns in the secondary coil divided by the number of turns in the primary coil.

Reading Check How does a transformer produce an alternating current in the secondary coil?

Step-Up Transformer A transformer that increases the voltage so that the output voltage is greater than the input voltage is a step-up transformer. In a step-up transformer, the number of wire turns on the secondary coil is greater than the number of turns on the primary coil. For example, the secondary coil of the step-up transformer in **Figure 22A** has twice as many turns as the primary coil has. The ratio of the output voltage to the input voltage is 2:1, and the output voltage is twice as large as the input voltage. For this transformer, an input voltage of 60 V in the primary coil is increased to 120 V in the secondary coil.

Step-Down Transformer A transformer that decreases the voltage so that the output voltage is less than the input voltage is a step-down transformer. In a step-down transformer, the number of wire turns on the secondary coil is less than the number of turns on the primary coil. In **Figure 22B** the secondary coil has half as many turns as the primary coil has, so the ratio of the output voltage to the input voltage is 1:2. The input voltage of 240 V in the primary coil is reduced to a voltage of 120 V in the secondary coil.

Figure 22 Transformers can increase or decrease voltage.

A A step-up transformer increases voltage. The secondary coil has more turns than the primary coil does. **B** A step-down transformer decreases voltage. The secondary coil has fewer turns than the primary coil does.

Infer whether a transformer could change the voltage of a direct current.

Teacher FYI

Eddy Currents Eddy currents can be generated in transformers by the changing magnetic field around the core. Because the magnetic fields generated by the eddy current oppose the original field, power is lost. The cores of transformers are often made out of many thin, laminated strips of metal instead of one big iron loop. Insulating glue between the strips restricts the eddy currents to individual strips, where they cannot grow very large. This makes the transformer more efficient.

Activity

Finding Transformers Take students outside and find the transformers leading into the school. Ask students to find the transformers near their homes as well, and compare them. Caution students to not touch or get too close to the transformers. **L1 ELL**

Visual-Spatial

Reading Check

Answer The changing magnetic field in the iron core induces an alternating current with the same frequency in the secondary coil.

Caption Answer

Figure 22 No, a direct current does not produce a changing magnetic field in the primary or secondary coil. Electromagnetic induction does not occur.

Active Reading

Write-Draw-Discuss This strategy encourages students to actively participate in reading and lectures, assimilating content creatively. Have students write about electric motors, generators, and transformers, clarify their ideas, then make illustrations or drawings. Ask students to share responses with the class and display several examples. **L2**

Post Reading

Concept Map Starting with the central term *electric current*, have students draw five lines, similar to bicycle wheel spokes, each with one of the following: electromagnetic induction, generator, DC, AC, and transformers. Using more branching lines, have students explain these terms.

Visual-Spatial Use **Figure 20** to tie the electric generator to the electric motor. Have students explain what each is used for and how each uses the connection between electricity and magnetism. L2 

Assessment

Content Ask students to work in teams to design a human-powered device for generating electrical energy. As an example, describe how a stationary bicycle could be modified to rotate the electromagnet in a generator. Use **Performance Assessment in the Science Classroom**, p. 117. L2

Figure 23 Many steps are involved in the creation, transportation, and use of the electric current in your home.

Identify the steps that involve electromagnetic induction.

Transmitting Alternating Current Power plants commonly produce alternating current because the voltage can be increased or decreased with transformers. Although step-up transformers and step-down transformers change the voltage at which electrical energy is transmitted, they do not change the amount of electrical energy transmitted. **Figure 23** shows how step-up and step-down transformers are used in transmitting electrical energy from power plants to your home.

section 3 review

Summary

From Mechanical to Electrical Energy

- An electric current is produced by moving a wire loop through a magnetic field or a magnet through a wire loop.
- A generator can produce an electric current by rotating a wire coil in a magnetic field.

Direct and Alternating Currents

- A direct current flows in one direction. An alternating current changes direction in a regular pattern.

Transformers

- A transformer changes the voltage of an alternating current. The voltage can be increased or decreased.
- The changing magnetic field in the primary coil of a transformer induces an alternating current in the secondary coil.

Self Check

1. **Describe** the energy conversions that occur when water falls on a paddle wheel connected to a generator that is connected to electric lights.
2. **Compare and contrast** a generator with an electric motor.
3. **Explain** why the output voltage from a transformer is zero if a direct current flows through the primary coil.
4. **Explain** why electric current produced by power plants is transmitted as alternating current.
5. **Think Critically** A magnet is pushed into the center of a wire loop and then stops. What is the current in the wire loop after the magnet stops moving? Explain.

Applying Math

6. **Use a Ratio** A transformer has 1,000 turns of wire in the primary coil and 50 turns in the secondary coil. If the input voltage is 2,400 V, what is the output voltage?

section 3 review

1. falling water strikes paddle wheel and wheel begins to turn—kinetic energy to mechanical energy; turning paddle wheel turns shaft of generator—mechanical energy to electrical energy; electrical energy flows to electric lights—electrical energy to heat and light
2. An electric motor converts electrical energy to mechanical energy and a generator converts mechanical energy to electrical energy.
3. Only an alternating current induces the voltage in the transformer.
4. Alternating current is used because transformers can increase or decrease

voltage. This enables power to be transmitted at high voltage to minimize the energy converted into heat. The voltage then is reduced to lower levels for safe use.

5. Zero; either the magnet or the wire loop must be moving to induce current.

$$\begin{aligned} \text{Voltage}_{\text{out}} &= \frac{\text{turns}_{\text{secondary}}}{\text{turns}_{\text{primary}}} \\ \frac{50}{1,000} &= \frac{\text{Voltage}_{\text{out}}}{2,400 \text{ V}} \\ \text{Voltage}_{\text{out}} &= 120 \text{ V} \end{aligned}$$

 M.A.A.1.4.4

Electricity and Magnetism

Huge generators in power plants produce electricity by moving magnets past coils of wire. How does this produce an electric current?

Real-World Problem

How can a magnet and a wire coil be used to produce an electric current?

Goals

- **Observe** how a magnet and a wire coil can produce an electric current in a wire.
- **Compare** the currents created by moving the magnet and the wire coil in different ways.

Materials

cardboard tube scissors
bar magnet galvanometer or ammeter
insulated wire

Safety Precautions

WARNING: Do not touch bare wires when current is running through them.

Procedure

1. Wrap the wire around the cardboard tube to make a coil of about 20 turns. Remove the tube from the coil.
2. Use the scissors to cut and remove 2 cm of insulation from each end of the wire.
3. Connect the ends of the wire to a galvanometer or ammeter. Record the reading on your meter.
4. Insert one end of the magnet into the coil and then pull it out. Record the current. Move the magnet at different speeds inside the coil and record the current.

5. Watch the meter and move the bar magnet in different ways around the outside of the coil. Record your observations.
6. Repeat steps 4 and 5, keeping the magnet stationary and moving the wire coil.

Conclude and Apply

1. How was the largest current generated?
2. Does the current generated always flow in the same direction? How do you know?
3. **Predict** what would happen if you used a coil made with fewer turns of wire.
4. **Infer** whether a current would have been generated if the cardboard tube had been left in the coil. Why or why not? Try it.

Communicating Your Data

Compare the currents generated by different members of the class. What was the value of the largest current that was generated? How was this current generated?

**BENCH
TESTED**

Video Lab available for this Lab.

Real-World Problem

Purpose Students observe electromagnetic induction of a current. **L1** **KS** **Kinesthetic**

Process Skills observe and infer, interpret data, draw conclusions, recognize cause and effect, compare and contrast, make models

Time Required 45 minutes

Alternate Materials One end of a horseshoe magnet can replace the bar magnet.

Procedure

Teaching Strategy Be sure the galvanometer is on the most sensitive scale and that students form complete circuits.

Conclude and Apply

1. Faster motion produces more current, as does moving the magnet in the coil rather than outside it.
2. No; the needle was deflected in different directions depending on whether the magnet moved in or out of the coil.
3. A smaller current would be induced.
4. Yes; electric and magnetic fields are not affected by the cardboard.

LAB 445

Assessment

Performance Ask each student to make a poster that shows the design of the experiment they used and explains what each piece of equipment does. To one side, they should list how changes in the setup change the current induced. Use PASC, p. 145. **L1**

Communicating Your Data

Ask students to include suggestions for how they could make a stronger current. Possible answers: increase the number of coils; make the coils closer to the moving magnet; use a stronger magnet

Real-World Problem

Purpose Students will assemble an electromagnet and then attempt to control its strength by changing its construction. L2

Kinesthetic

Process Skills form a hypothesis, identify and manipulate variables, make and use tables, observe

Time Required 60 minutes

Possible Materials Iron 16-penny nails are available through science supply companies. If nails are purchased locally, make sure they are made of iron.

Alternate Materials Students can use either an electric power supply or batteries for the electric current in their electromagnets. A knife switch can be included for easier current control.

Safety Precautions Closely monitor students who are using an electric power supply to ensure that they do not apply more than 6 volts.

Form a Hypothesis

Possible Hypothesis The more loops that are used in the construction of the electromagnet the stronger the magnetic field it will generate.

CONTROLLING ELECTROMAGNETS

Real-World Problem

You use electromagnets every day when you use stereo speakers, power door locks, and many other devices. To make these devices work properly, the strength of the magnetic field surrounding an electromagnet must be controlled. How can the magnetic field produced by an electromagnet be made stronger or weaker? Think about the components that form an electromagnet. Make a hypothesis about how changing these components would affect the strength of the electromagnet's magnetic field.

Form a Hypothesis

As a group, write down the components of an electromagnet that might affect the strength of its magnetic field.

Test Your Hypothesis

Make a Plan

1. Write your hypothesis about the best way to control the magnetic field strength of an electromagnet.
2. **Decide** how you will assemble and test the electromagnets. Which features will you change to determine the effect on the strength of the magnetic fields? How many changes will you need to try? How many electromagnets do you need to build?
3. **Decide** how you are going to test the strength of your electromagnets. Several ways are possible with the materials listed. Which way would be the most sensitive? Be prepared to change test methods if necessary.

Goals

- **Measure** relative strengths of electromagnets.
- **Determine** which factors affect the strength of an electromagnet.

Possible Materials

22-gauge insulated wire
16-penny iron nail
aluminum rod or nail
0-6 V DC power supply
three 1.5-V D cells
steel paper clips
magnetic compass
duct tape (to hold D cells together)

Safety Precautions

WARNING: Do not leave the electromagnet connected for long periods of time because the battery will run down. Magnets will get hot with only a few turns of wire. Use caution in handling them when current is flowing through the coil. Do not apply voltages higher than 6 V to the electromagnets.

Alternative Inquiry Lab

Using Electromagnets Extend this Lab into an Inquiry Lab by building on the experience gained performing this lab. Encourage your students to use what they have learned to brainstorm uses for electromagnets. Have student groups each choose one question to explore. Ask them to list

the materials they need to explore their questions. Unsafe or impractical questions should be eliminated. Students should have their plans for their additional experiments approved before continuing. Conduct the experiments after all necessary materials have been gathered. L3

Using Scientific Methods

- Write your plan of investigation. Make sure your plan tests only one variable at a time.

Follow Your Plan

- Before you begin to build and test the electromagnets, make sure your teacher approves of your plan.
- Carry out your planned investigation.
- Record your results.

Analyze Your Data

- Make a table** showing how the strength of your electromagnet depends on changes you made in its construction or operation.
- Examine** the trends shown by your data. Are there any data points that seem out of line? How can you account for them?

Testing Electromagnets

Trial	Electromagnet Construction Features	Strength of Electromagnet
-------	-------------------------------------	---------------------------

Student answers will vary.

Conclude and Apply

- Describe** how the electromagnet's magnetic-field strength depended on its construction or operation.
- Identify** the features of the electromagnet's construction that had the greatest effect on its magnetic-field strength. Which do you think would be easiest to control?
- Explain** how you could use your electromagnet to make a switch. Would it work with both AC and DC?
- Evaluate** whether or not your results support your hypothesis. Explain.

Communicating Your Data

Compare your group's result with those of other groups. Did any other group use a different method to test the strength of the magnet? Did you get the same results?

LAB 447

Assessment

Process Students should research how a doorbell works and make drawings illustrating what they find. Use **Performance Assessment in the Science Classroom**, p. 127. L2

Communicating Your Data

When comparing various methods used to test the strength of the magnet, students should consider the masses of the objects used and their composition. L2

Test Your Hypothesis

Possible Procedures Wrap wire around a nail about 15 times. Tape it in place, leaving about 20 cm loose on each end. Connect the wire ends to the terminals of a battery.

Determine how many paper clips the magnetized nail will pick up. Vary the number of wire loops and the number of batteries to observe the effect on the strength of the nail's magnetization.

Teaching Strategy Remind students that the polarity of the electromagnet can be reversed by changing the direction of the current flow.

Expected Outcome Increasing the number of loops in the electromagnet or the number of batteries increases the strength of the magnetic field.

Analyze Your Data

- Check each group's table.
- Answers will vary.

Error Analysis Have students compare their results and their hypotheses and explain why differences occurred.

Conclude and Apply

- The strength of the magnetic field increased when the number of loops or number of batteries increased.
- Adding additional batteries had the greatest effect and would be easiest to control.
- Accept all reasonable responses. One way would be to use the electromagnet to pull a metal strip to close a circuit. Without current, a spring pulls the strip back and opens the circuit.
- Answers will vary.

LAB 447

Content Background

Magnetic resonance imaging (MRI) is a noninvasive diagnostic technique that uses nuclear magnetic resonance (NMR) to image the structure of the body. Unhindered by bone and capable of producing images in a variety of planes, MRI is used in the diagnosis of brain tumors and disorders, spinal disorders, multiple sclerosis, and cardiovascular diseases. The procedure is considered to be without risk to the patient.

Types of magnetic resonance include electron paramagnetic resonance (EPR), also known as electron spin resonance (ESR), involving the magnetic effect of electrons, and nuclear magnetic resonance (NMR), involving the magnetic effects of protons and neutrons in the nuclei of atoms. The NMR resonant frequency provides information about the molecular material in which the nuclei reside.

Discussion

X Rays How are X rays used differently from MRI? **Possible Answer:** X rays are used for the diagnosis of problems in hard tissue areas of the body while MRI is used to diagnose soft tissue disorders. **[L2] Logical-Mathematical**

Historical Significance

Make sure students understand that MRI has only been developed in the last twenty-five years, which is a very short period of time in the span of history. Start a discussion that will get students to think about the medical advances that have been made possible by MRI. For example, because of MRI doctors are now able to diagnose birth defects and operate on babies in the womb.

Body Art

The surgeon turns the computer screen so the patient can see it. Pointing to a colorful image of the patient's brain, she reassures the worried patient. "This MRI shows exactly where your tumor is. We can remove it with little danger to you."

MRI for the Soft Stuff

MRI stands for "magnetic resonance imaging." It's a way to take 3-D pictures of the inside of your body. Before the 1980s, doctors could x-ray solid tissue such as bones, but had no way to see soft tissue such as the brain. Well, they had one way—surgery, which sometimes caused injury and infection, risking a patient's health.

MRI uses a strong magnet and radio waves. Tissues in your body contain water molecules that are made of oxygen and hydrogen atoms.

The nucleus of a hydrogen atom is a proton, which behaves like a tiny magnet. A strong magnetic field inside the MRI tube makes these proton magnets line up in the direction of the field. Radio waves are then applied to the body. The protons absorb some of the radio-wave energy, and flip their direction.

When the radio waves are turned off, the protons realign themselves with the magnetic field and emit the energy they absorbed. Different tissues in the body absorb and emit different amounts of energy. The emitted energy is detected, and a computer uses this information to form images of the body.

Your brain is getting bigger!

MRI has turned into an important research tool. For example, researchers using MRI have found that the brain grows rapidly through adolescence. Before this research, people thought that the brain stopped growing in childhood. MRI has proved that adolescents are getting bigger brains all the time.

This patient is about to be placed in an MRI machine.

Interview As an oral history project, interview a retired physician or surgeon. Ask him or her to discuss with you how tools such as MRI changed during his or her career. Make a list of the tools and how they have helped improve medicine.

Interview If any of the students' parents work in the health field, ask them for suggestions of people students can interview. Conduct a brainstorming session to establish questions for the students to ask during their interviews to help them focus on relevant facts. Encourage them to write down their questions before the interview to ease this process. **[L2]**

Functional MRI (Medical Radiology) by C.T.W. Moonen (Editor) and P.A. Bandettini (Editor). Springer-Verlag, 2000

Imaging of Soft Tissue Tumors by A.M.A. De Schepper, and others, eds. Springer Verlag 2001

Reviewing Main Ideas

Section 1 Magnetism

1. A magnetic field surrounds a magnet and exerts a magnetic force.
2. All magnets have two poles: a south pole and a north pole.

3. Opposite poles of magnets attract; like poles repel.
4. Groups of atoms with aligned magnetic poles are called magnetic domains.

Section 2 Electricity and Magnetism

1. An electric current flowing through a wire produces a magnetic field.
2. An electric current passing through a coil of wire can produce a magnetic field inside the coil. The coil becomes an electromagnet. One end of the coil is the north pole, and the other end is the south pole.

3. The magnetic field around an electromagnet depends on the current and the number of coils.

4. An electric motor contains a rotating electromagnet that converts electrical energy to mechanical energy.

Section 3 Producing Electric Current

1. By moving a magnet near a wire, you can create an electric current in the wire. This is called electromagnetic induction.

2. A generator produces electric current by rotating a coil of wire in a magnetic field. Generators at the base of this dam convert the kinetic energy in falling water into electrical energy.
3. Direct current flows in one direction through a wire; alternating current reverses the direction of current flow in a regular pattern.
4. The number of turns of wire in the primary and secondary coils of a transformer determines whether it increases or decreases voltage.

FOLDABLES Use the Foldable that you made at the beginning of this chapter to help you review magnets and magnetism.

CHAPTER STUDY GUIDE 449

Identifying Misconceptions

After students have done the lab on page 422F and completed the chapter, have them perform this lab.

Materials PVC pipe, aluminum or copper pipe, circular magnet

Procedure Drop a circular magnet down the

length of each pipe and note how long it takes to get to the bottom.

Expected Outcome The magnet travels slower down the metal tube because the falling magnet creates an electric current in the pipe, which creates a magnetic field that slows it down. **L2**

Assess

Reviewing Main Ideas

Assessment

Assessment Transparency Magnetism Chapter 14

Directions: Carefully read the diagram and answer the following questions.

1. What is this experiment intended to prove?
 A. that a clamp stand can hold a magnet
 B. that a cotton thread can support a paperclip in midair
 C. that a magnet can overcome the force of gravity
 D. that a paper clip can float in midair on its own
2. According to the diagram, what is happening to the paperclip?
 E. It is falling.
 G. It is rising.
 H. It is changing shape.
 I. It is suspended between the force of the magnet and the cotton thread restraining it.
3. What would happen to the paperclip if the cotton thread was removed?
 A. It would fall.
 B. It would rise until it came in contact with the magnet.
 C. It would continue to rise beyond the magnet.
 D. It would remain suspended where it is.

L2

FOLDABLES Have students use their Foldables to review the content of the chapter. On the back of the paper, have students write a paragraph describing how electric motors and electric generators work.

Using Vocabulary

1. transformer
2. magnetic pole
3. Direct current
4. magnetism
5. solenoid
6. magnetic domain
7. galvanometer

Checking Concepts

8. A
9. A
10. C
11. D
12. B
13. B
14. C

Interpreting Graphics

15. Both use a coil, an electromagnet, and a permanent magnet; in both cases the magnets move relative to one another. In an AC generator, a force turns one of the magnets, generating alternating electric current in the electromagnet. In a DC motor, electricity causes a magnet to turn, thereby turning whatever is attached to it.
16. permanent magnet—forces the electromagnet to spin; electromagnet—creates magnetic poles that try to align with the poles of the permanent magnet; the poles switch causing the electromagnet to spin which turns a shaft; current source—provides the electric current that creates the electromagnet
17. See Figure 15.
18. about 8 μT
19. The magnetic field strength decreases more rapidly closer to the wire. The magnetic field strength plunges until about 6 cm, then the strength begins to level off to about 2 μT .
20. 2 μT

SCC 243

Using Vocabulary

- | | |

FCAT Vocabulary

Complete each statement with the correct vocabulary word or phrase.

1. A(n) _____ can be used to change the voltage of an alternating current.
2. A(n) _____ is the region where the magnetic field of a magnet is strongest.
3. _____ does not change direction.
4. The properties and interactions of magnets are called _____.
5. A(n) _____ can rotate in a magnetic field when a current passes through it.
6. The magnetic poles of atoms are aligned in a(n) _____.
7. A device that uses an electromagnet to measure electric current is a(n) _____.

Checking Concepts

Choose the word or phrase that best answers the question.

8. Where is the magnetic force exerted by a magnet strongest?
 - A) both poles
 - B) south pole
 - C) north pole
 - D) center
9. Which change occurs in an electric motor?
 - A) electrical energy to mechanical energy
 - B) thermal energy to wind energy
 - C) mechanical energy to electrical energy
 - D) wind energy to electrical energy

10. What happens to the magnetic force as the distance between two magnetic poles decreases?
 - A) remains constant
 - B) decreases
 - C) increases
 - D) becomes zero
11. Which of the following best describes what type of magnetic poles the domains at the north pole of a bar magnet have?
 - A) north magnetic poles only
 - B) south magnetic poles only
 - C) no magnetic poles
 - D) north and south magnetic poles
12. Which of the following would not change the strength of an electromagnet?
 - A) increasing the amount of current
 - B) changing the current's direction
 - C) inserting an iron core inside the coil
 - D) increasing the number of loops
13. Which of the following is NOT part of a generator?
 - A) turbine
 - B) battery
 - C) electromagnet
 - D) permanent magnet
14. Which of the following describes the direction of the electric current in AC?
 - A) is constant
 - B) is direct
 - C) changes regularly
 - D) changes irregularly

Interpreting Graphics

15. Copy and complete the Venn diagram below. Include the functions, part names, and power sources for these devices.

Use the ExamView® Pro Testmaker CD-ROM to:

- create multiple versions of tests
- create modified tests with one mouse click for inclusion students
- edit existing questions and add your own questions
- build tests aligned with state standards using built-in State Curriculum Tags
- change English tests to Spanish with one mouse click and vice versa

Use the diagram below to answer questions 16 and 17.

- 16. Describe** Using the diagram, describe the function of the permanent magnet, the electromagnet, and the current source in a simple electric motor.
- 17. Describe** the sequence of steps that occur in an electric motor that forces the coil to spin. Include the role of the commutator in your description.

Use the graph below to answer questions 18–20.

- 18. Explain** How much larger is the magnetic field strength 1 cm from the wire compared to 5 cm from the wire?
- 19. Explain** Does the magnetic field strength decrease more rapidly with distance closer to the wire or farther from the wire? Explain.
- 20. Solve** Using the graph, estimate the magnetic field strength 11 cm from the wire.

More Chapter Review fl.gpscience.com

Thinking Critically

- 21. Infer** how you could use a horseshoe magnet to find the north direction.
- 22. Explain** In Europe, generators produce alternating current at a frequency of 50 Hz. Would the electric appliances you use in North America work if you plugged them into an outlet in Europe? Why or why not?
- 23. Predict** Two generators are identical except for the loops of wire that rotate through their magnetic fields. One has twice as many turns of wire as the other one does. Which generator will produce the most electric current? Why?
- 24. Explain** why a bar magnet will attract an iron nail to either its north pole or its south pole, but it will attract another magnet to only one of its poles.
- 25. Compare and contrast** electromagnetic induction and the formation of electromagnets.

Applying Math

- 26. Calculate** A step-down transformer reduces a 2,400-V current to 120 V. If the primary coil has 500 turns of wire, how many turns of wire are there on the secondary coil?
- 27. Use a Ratio** To produce a spark, a spark plug requires a current of about 12,000 V. A car's engine uses a type of transformer called an induction coil to change the input voltage from 12 V to 12,000 V. In the induction coil, what is the ratio of the number of wire turns on the primary coil to the number of turns on the secondary coil?

CHAPTER REVIEW 451

Thinking Critically

- 21.** Possible answer: suspend it by the middle so it can rotate; the south end should be attracted to magnetic north
- 22.** No; North American appliances do not work in Europe unless they are made to operate at both frequencies. If the appliance is designed for dual operation, only an adapter is required. Most North American appliances require adapters, a converter, and a transformer to adjust the current and to accommodate the outlet designs in Europe.
- 23.** The generator with twice as many loops will produce the most current because more wire loops pass through the magnetic field.
- 24.** The magnetic domains in the nail become aligned so they are always attracted to the nearest pole of the bar magnet. The domains in a bar magnet are aligned in a fixed direction.
- 25.** Both are related to current flowing in a wire. Electromagnetic induction is the generation of a current by a changing magnetic field. An electromagnet is formed when a wire is wrapped around an iron core and current flows through the wire.

Applying Math

Math Standards

National: 1, 2, 9

Florida: MA.A.1.4.4, MA.D.1.4.1

$$26. \frac{\text{Voltage}_{\text{out}}}{\text{Voltage}_{\text{in}}} = \frac{\text{turns}_{\text{secondary}}}{\text{turns}_{\text{primary}}}$$

$$\frac{120 \text{ V}}{2,400 \text{ V}} = \frac{\text{turns}_{\text{secondary}}}{500 \text{ turns}}$$

$$\text{turns}_{\text{secondary}} = 25 \text{ turns}$$

- 27.** Use the reciprocal of the equation in problem 26.

$$\frac{\text{turns}_{\text{primary}}}{\text{turns}_{\text{secondary}}} = \frac{\text{Voltage}_{\text{in}}}{\text{Voltage}_{\text{out}}}$$

$$\frac{\text{turns}_{\text{primary}}}{\text{turns}_{\text{secondary}}} = \frac{12 \text{ V}}{12,000 \text{ V}} = \frac{1}{1000}$$

the ratio is 1:1,000

1. C 3. B
2. C 4. B

Record your answers on the answer sheet provided by your teacher or on a sheet of paper.
The assessed Florida Benchmark appears above the question.

Multiple Choice

A transformer has 50 turns of wire on the primary coil and 10 turns of wire on the secondary coil. The effect of changing the input voltage is summarized in the table below.

Use the table below to answer questions 1 and 2.

Voltage and Current in a Transformer				
Trial	Input Voltage (V)	Primary Coil Current (A)	Output Voltage (V)	Secondary Coil Current (A)
1	5	0.1	1	0.5
2	10	0.2	2	1.0
3	20	0.2	4	1.0
4	50	0.5	10	2.5

SC.2.14.3

1. What is the ratio of the input voltage to the output voltage for this transformer?

- A. 1:2.5
B. 4:1
C. 5:1
D. 1:5

SC.2.14.3

2. What is the ratio of the secondary-coil current to the primary-coil current?

- A. the ratio of the secondary-coil wire turns to the primary-coil wire turns
B. the ratio of the output voltage to the input voltage
C. the ratio of the primary-coil wire turns to the secondary-coil wire turns
D. It always equals one.

Use the figure below to answer question 3.

3. A steel paper clip is sitting on a desk. The figure above shows the magnetic domains in a section of the paper clip after the north pole of a magnet has been moved close to it. According to the diagram, the magnet's north pole is at which position?

- A. position 1
B. position 2
C. position 3
D. position 4

4. A hydroelectric power plant uses water to spin a turbine attached to a generator. The generator produces 30,000 kW of electric power. If the turbine and generator are a combined 75 percent efficient, how much power does the falling water supply to the turbine?

- A. 50,000 kW
B. 40,000 kW
C. 22,500 kW
D. 20,000 kW

Gridded Response

Use the figure below to answer questions 5 and 6.

- A step-down transformer is plugged into a 120-V electric outlet and a lightbulb is connected to the output coil. The transformer has 20 turns on the primary coil and 2 turns on the secondary coil. What is the voltage, in volts, at the output coil?
- If the lightbulb has a resistance of $8\ \Omega$, what is the current, in amperes, in the lightbulb?

Short Response

- A bicycle has a small electric generator that is used to light a headlight. The generator is made to spin by rubbing against a wheel. Will the bicycle coast farther on a level surface if the light is turned on or turned off?
- A student connects a battery to a step-up transformer to boost the voltage. Explain why a small electric motor does not spin when it is connected to the secondary coil of the transformer.

Extended Response

Use the figure below to answer question 9.

- The graphic above shows how the voltage produced by a generator depends on the rotation rate of the coil. Explain whether this generator could produce household AC current that is 120 V at 60 Hz.
- Compare and contrast the behavior and properties of positive and negative electric charges with north and south magnetic poles.

Test-Taking Tip

Read All the Information If a question includes a text passage and a graphic, carefully read the information in the text passage and the graphic before answering the question.

Question 1 Review the information in the text above the table and the information in the table.

Gridded Response

- First find the output voltage:

$$\frac{\text{Voltage}_{\text{out}}}{\text{Voltage}_{\text{in}}} = \frac{\text{turns}_{\text{secondary}}}{\text{turns}_{\text{primary}}}$$

$$\text{so: voltage}_{\text{out}} =$$

$$(\text{voltage}_{\text{in}}) \times \frac{(\text{turns}_{\text{secondary}})}{(\text{turns}_{\text{primary}})}$$

$$= (120\ \text{V}) \times \frac{(2\ \text{turns})}{(20\ \text{turns})}$$

$$= 12\ \text{V}$$

- Use Ohm's law to find the current.

$$I = \frac{V}{R} = \frac{(12\ \text{V})}{(8\ \Omega)} = 1.5\ \text{A}$$

Short Response

- The kinetic energy of the coasting bicycle is converted into electrical energy if the generator is turned on. The bicycle will coast farther if the generator is turned off and the generator is not reducing the kinetic energy at a quicker rate.
- Only an alternating current can induce a voltage in the secondary coil of a transformer. A battery supplies a direct current, so the output voltage is zero and no current flows.

Extended Response

- When the generator is rotating at 60 Hz, it produces 12 V. Therefore this generator could not produce household AC current.
- Similarities:** Types of electric charge exist, positive and negative. Two types of magnetic poles exist, north and south. Electric charges exert forces on each other. Magnetic poles exert forces on each other. Like charges repel and unlike attract. Like poles repel, unlike attract. **Differences:** positive and negative charges exist separately, north and south poles don't exist separately.

Rubrics

For more help evaluating Short- and Extended-Response questions, see the rubrics on p. 9T.

Section Focus Transparency Chapter 15

Rainbows

Have you ever noticed how a rainbow is the only spectrum of visible light that you can see? The colors that compose visible light (red, orange, yellow, green, blue, indigo, and violet) are all part of the same spectrum of light. The only difference is the wavelength of the light. The colors that compose visible light are all part of the same spectrum of light. The only difference is the wavelength of the light.

1. Looking at the photo, which color of light bends the most as it passes through the prism? Which color bends the least?

2. Light is a type of wave. What other kinds of waves can you think of?

3. What do all these waves have in common? What are some possible differences?

L2

Section Focus Transparency Chapter 15

Whoa, Not So Fast!

Radio waves are part of the electromagnetic spectrum. These waves are the same as all other waves, but they are much longer. They are also much slower than most other waves. They are also much slower than most other waves. They are also much slower than most other waves.

1. Which of the following is the fastest? (a) electromagnetic waves (b) sound waves (c) light waves (d) radio waves

2. Is the speed of a radio wave the same as the speed of light? If not, how fast is it?

3. The prefix *radio* means *radio*. What does the prefix *radio* mean? (a) radio (b) radio (c) radio (d) radio

L2

Section Focus Transparency Chapter 15

Could it be a growth spurt?

The Global Positioning System (GPS) uses electromagnetic waves and satellites to determine locations and measurements on Earth. For example, only a few scientists found that Mount Everest is actually 28,169 feet tall, 21 m higher than the figure accepted since 1954. This man is demonstrating another use of the GPS. By connecting a receiver to a computer, he is able to map his location.

1. Name some ways people might use the GPS.

2. Could the GPS function using sound waves? Explain.

L2

Assessment Transparency Chapter 15

Electromagnetic Waves

Directions: Carefully review the table and answer the following questions.

Type of wave	Wavelength range (m)
Gamma rays	10^{-11} - 10^{-14}
X rays	10^{-8} - 10^{-11}
Ultraviolet	10^{-8} - 10^{-7}
Infrared	10^{-6} - 10^{-3}
Microwave	10^{-2} - 10^{-1}
Radio wave	10^1 - 10^3

1. Which of the following wavelengths could be broadcast by a rock-and-roll radio station?

A. 10^{-11} meters B. 10^{-8} meters C. 10^{-6} meters D. 10^{-3} meters

2. If a device emits an electromagnetic wave with a wavelength of 10^{-11} meters, then it is probably:

A. an X-ray machine B. an AM-FM car radio C. a microwave D. a light bulb

3. Food can be heated rapidly in your own home using an electromagnetic wave with a wavelength of:

A. 10^{-11} B. 10^{-8} C. 10^{-6} D. 10^{-3}

Key to Teaching Strategies

The following designations will help you decide which activities are appropriate for your students.

- L1** Level 1 activities should be appropriate for students with learning difficulties.
- L2** Level 2 activities should be within the ability range of all students.
- L3** Level 3 activities are designed for above-average students.
- ELL** ELL activities should be within the ability range of English Language Learners.
- COOP LEARN** Cooperative Learning activities are designed for small group work.
- LS** Multiple Learning Styles logos, as described on page 12T, are used throughout to indicate strategies that address different learning styles.
- P** These strategies represent student products that can be placed into a best-work portfolio.
- PBL** Problem-Based Learning activities apply real-world situations to learning.

➤ Before You Read

Light is electromagnetic. Is light a magnetic wave? Is it an electric wave? Is it both? Write down your ideas before reading.

➤ Read to Learn

How do sound and water waves move?

Sound is made when something vibrates. Water waves move energy from one place to another, and so do sound and water waves. Sound travels faster than water waves in this category. Liquid sound waves can travel through matter, but water waves can travel through water and land. Sound waves can travel through matter, but water waves can travel through water and land. Sound waves can travel through matter, but water waves can travel through water and land.

How are electromagnetic waves made?

Electromagnetic waves are made by vibrating electric charges. Electromagnetic waves are made by vibrating electric charges. Electromagnetic waves are made by vibrating electric charges. Electromagnetic waves are made by vibrating electric charges.

1 Apply your scientific method skills to the resources.

Science Content Background

section What are electromagnetic waves?

Waves in Space

Throughout history, people have learned about the universe from the visible light that reached their eyes. For the past 100 years, people have been able to detect other types of electromagnetic radiation as well. Instruments such as radio telescopes and ultraviolet detectors have made this possible.

The Nature of Electromagnetic Waves

Electricity and magnetism are related. For example, a moving electric charge produces a magnetic field. James Clerk Maxwell in the 1860s realized that a changing electric field can produce a magnetic field. He also realized that because changing electric and magnetic fields can create each other, an electromagnetic wave that consisted only of oscillating electric and magnetic fields could exist.

An electromagnetic wave can be produced by an electric charge that is moving back and forth. The oscillating charge produces a changing electric field. The changing electric field produces a changing magnetic field, which produces a changing electric field and so on. In this way, the electric and magnetic fields oscillate in time and induce each other.

The two fields oscillate perpendicular to each other and perpendicular to the direction the wave is traveling. The frequency of the wave is the frequency at which the fields oscillate.

section The Electromagnetic Spectrum

Infrared Waves

All objects emit electromagnetic waves. The warmer an object is, the more radiation it emits. Infrared waves are emitted by heat lamps at fast-food restaurants to keep food warm. Remote control devices use infrared waves to send signals that control TVs, VCRs and stereo equipment.

Snakes in the pit viper family, which includes rattlesnakes, have “pits” in their heads that allow them to detect infrared radiation. They use this ability when hunting small, warm-blooded mammals in dark tunnels.

Ultraviolet Waves

Skin cells contain melanocytes, which form the pigment melanin when exposed to UV rays. Melanin causes people to tan, and it blocks some UV radiation. Some insects, such as bees, can see UV radiation.

X Rays and Gamma Rays

Radiation detectors use the tendency of X rays and gamma rays to ionize atoms as a means for detection. Workers who may be exposed to these types of radiation often wear radiation badges. The badges are periodically developed to determine the total amount of radiation the worker has been exposed to.

Radio Communication

Radio Transmission

Although Guglielmo Marconi was given credit for inventing radio, much of the credit should be given to Nikola Tesla. Tesla invented the means to turn electrical energy into radio waves.

Antennae are made of materials that are good conductors of electricity, so they allow easy movement of electrons. Electrons accelerating up and down a vertical antenna produce radio waves. If an antenna is aligned vertically, incoming radio waves cause the electrons to accelerate up and down the antenna. For a 1.5 million Hz AM radio wave, the electrons move up and down 1.5 million times per second.

AM radio has a relatively small frequency range of 1.165 MHz, and FM has a range of 20 MHz. The AM band is fine for voices, but the FM band is better for listening to music because it produces a richer sound.

On some nights you can pick up AM stations several hundred miles from where

they are broadcast. This is because AM radio waves reflect off the ionosphere. FM radio waves are not reflected by the ionosphere and need to travel in a straight line to reach a receiver. This limits their range.

Teacher to Teacher

Dr. Judith Doyle, Retired Teacher
Newark High School
Newark, Ohio

"To demonstrate how microwaves impact water molecules, place a marshmallow on a paper plate into a microwave and cook for two minutes at 50%-60% power. The marshmallow will expand rapidly, deflate slightly during off cycles, and then inflate more each time power resumes. (Microwaves vary, so test different power levels beforehand to determine best visual effect.) Microwaves cause the water molecules in the marshmallow to flip billions of times per second which in turn causes them to bump into each other and warm up, so as the marshmallow warms up, it expands."

How's the reception?

These giant 25-m dishes aren't picking up TV signals, unless they're coming from distant stars and galaxies. They are part of a group of 27 antennas that detect radio waves, which are electromagnetic waves. However, all objects emit electromagnetic waves, not just stars and galaxies.

Science Journal List six objects around you that emit light or feel warm.

Theme Connection

Energy Electromagnetic waves transfer energy. The electromagnetic spectrum ranges from low-energy radio waves to high-energy gamma rays. People often use low-energy radio waves for communication.

About the Photo

The VLA These receiver dishes are part of the Very Large Array (VLA) radio telescope, located near Socorro, New Mexico. The 27 separate receivers together gather radio waves emitted by stars, galaxies, and other deep-space objects. Images are formed from the data that show details of the radio wave emission from the objects being studied. To view images produced by the VLA go to fl.gpscience.com and follow the links to your chapter.

Start-Up Activities

Can electromagnetic waves change materials?

You often hear about the danger of the Sun's ultraviolet rays, which can damage the cells of your skin. When the exposure isn't too great, your cells can repair themselves, but too much at one time can cause a painful sunburn. Repeated overexposure to the Sun over many years can damage cells and cause skin cancer. In the lab below, observe how energy carried by ultraviolet waves can cause changes in other materials.

1. Cut a sheet of red construction paper in half.
2. Place one piece outside in direct sunlight. Place the other in a shaded location.
3. Keep the construction paper in full sunlight for at least 45 min. If possible, allow it to stay there for 3 h or more before taking it down. Be sure the other piece remains in the shade.
4. **Think Critically** In your Science Journal, describe any differences you notice in the two pieces of construction paper. Comment on your results.

FOLDABLES[™] Study Organizer

Electromagnetic Waves

Make the following Foldable to help you understand electromagnetic waves.

- STEP 1** Fold a sheet of paper vertically in half from top to bottom.

- STEP 2** Fold in half from side to side with the fold at the top.

- STEP 3** Unfold the paper once. Cut only the fold of the top flap to make two tabs.

- STEP 3** Write on the front tabs as shown.

Identify Questions As you read the chapter, write answers to the questions on the back of the appropriate tabs.

Science online

Preview this chapter's content and activities at fl.goescience.com

Purpose Students observe how electromagnetic waves from the Sun affect the dye in colored paper. **L1 ELL LS Visual-Spatial**

Materials Although any color of construction paper will work for this activity, red will show the most dramatic results. Be sure to use construction paper that has not previously been exposed to sunlight.

Teaching Strategies

- Construction paper that is exposed to sunlight through a window will fade more slowly than construction paper in direct sunlight. The glass blocks much of the ultraviolet light.
- The construction paper should be exposed to sunlight for as long as possible. If time permits, allow students to observe the effects after different time intervals.

Think Critically

The color of the construction paper exposed to the Sun is faded compared to that of the paper left in the shade. Ultraviolet waves from the Sun have broken down some of the dye molecules.

Assessment

Process Ask students to compare how the ultraviolet waves affected the construction paper with what happens to their skin when they stay out too long in the Sun. Use **Performance Assessment in the Science Classroom**, p. 89.

Tie to Prior Knowledge

Magnets Show students how a magnet pulls on a nearby paper clip, even if they are not touching. Remind students that this is because a magnetic field surrounds the magnet. Tell students that in this section they will learn about magnetic fields and electric fields.

Word Analysis Write the term *electromagnetic wave* on the board. Ask students to study the word closely, and then infer which forces are involved in producing this type of wave. *electric and magnetic* Make sure students know the meanings of each of the word parts.

What are electromagnetic waves?

Reading Guide

FCAT Vocabulary

What You'll Learn

- Describe** how electric and magnetic fields form electromagnetic waves.
- Explain** how vibrating charges produce electromagnetic waves.
- Describe** properties of electromagnetic waves.

Why It's Important

You, and all the objects and materials around you, are radiating electromagnetic waves.

Review Vocabulary

hertz: the SI unit of frequency, abbreviated Hz; 1 Hz equals one vibration per second

New Vocabulary

- electromagnetic wave**
- radiant energy
- photon

Waves in Space

Stay calm. Do not panic. As you are reading this sentence, no matter where you are, you are surrounded by electromagnetic waves. Even though you can't feel them, some of these waves are traveling right through your body. They enable you to see. They make your skin feel warm. You use electromagnetic waves when you watch television, talk on a cordless phone, or prepare popcorn in a microwave oven.

Sound and Water Waves Waves are produced by something that vibrates, and they transmit energy from one place to another. Look at the sound wave and the water wave in **Figure 1**. Both waves are moving through matter. The sound wave is moving through air and the water wave through water. These waves travel because energy is transferred from particle to particle. Without matter to transfer the energy, waves cannot move.

Figure 1 Water waves and sound waves require matter to move through. Energy is transferred from one particle to the next as the wave travels through the matter.

Electromagnetic Waves However, electromagnetic waves do not require matter to transfer energy. **Electromagnetic waves** are made by vibrating electric charges and can travel through space where matter is not present. Instead of transferring energy from particle to particle, electromagnetic waves travel by transferring energy between vibrating electric and magnetic fields.

A magnetic field surrounds all magnets.

An electric field surrounds all charges.

Figure 2 Fields enable magnets and charges to exert forces at a distance. These fields extend throughout space.

Explain how you could detect a magnetic field.

Electric and Magnetic Fields

When you bring a magnet near a metal paper clip, the paper clip moves toward the magnet and sticks to it. The paper clip moves because the magnet exerts a force on it. The magnet exerts this force without having to touch the paper clip because all magnets are surrounded by a magnetic field, as shown in **Figure 2**. Magnetic fields exist around magnets even if the space around the magnets contains no matter.

Just as magnets are surrounded by magnetic fields, electric charges are surrounded by electric fields, also shown in **Figure 2**. An electric field enables charges to exert forces on each other even when they are far apart. Just as a magnetic field around a magnet can exist in empty space, an electric field exists around an electric charge even if the space around it contains no matter.

Magnetic Fields and Moving Charges

Electric charges also can be surrounded by magnetic fields. It is the motion of electrons that generates the magnetic field. An electric current, the net flow of electrons in one direction, is always surrounded by a magnetic field. In fact, any moving electric charge is surrounded by a magnetic field, as well as an electric field. For example, an electric current flowing through a wire is surrounded by a magnetic field, as illustrated in **Figure 3**.

Figure 3 Electrons moving in a wire are surrounded by a magnetic field.

Describe how you would confirm that a magnetic field exists around a current-carrying wire.

2 Teach

Caption Answers

Figure 2 Place a magnet where the field exists and see if there is a force exerted on the magnet.

Figure 3 Bring a compass near the wire.

Quick Demo

Seeing Magnetic Fields

Materials iron filings, iron bar magnet, plexiglass (optional: overhead projector, plastic wrap)

Estimated Time ten minutes

Procedure If using overhead, wrap writing surface with plastic wrap to protect. Place bar magnet on overhead or other flat surface. Lay plexiglass on top of magnet, and lightly sprinkle with iron filings above magnet. Point out how magnetic field drops off rapidly as distance from magnet increases. **L2** **IS** **Visual-Spatial**

IDENTIFYING

Misconceptions

No Magnetic Charge Students may believe that, since an electric field surrounds an electric charge, a magnetic field surrounds a magnetic charge. Explain that there is no magnetic charge. Magnetism is caused by moving electric charges. This is true even for magnetic materials. Electrons in all atoms move in a way that induces a small magnetic field. In most materials, these fields cancel, but in magnetic materials the atoms are arranged so that the fields combine to form a macroscopic field.

Differentiated Instruction

Challenge Have students research scientists who did early investigations on the relationship between electricity and magnetism, such as Oersted, Faraday, and Henry. Have students select an early experiment to demonstrate. **L3**

Mini LAB

Purpose Students investigate the behavior of electromagnetic waves. **L2 ELL MS Kinesthetic**

Materials television with remote control, glass, book, paper, metal pan

Teaching Strategy Suggest that students hold the objects both very close to the receiver and farther away from it. This will enable them to observe how the beam spreads out and can travel around objects.

Analysis

1. No (for most), because the infrared beam spreads out as it leaves its source.
2. The signal will travel through transparent or translucent materials.

Assessment

Process Some receivers are more sensitive and require the remote to be aimed directly at them. Ask students to suggest ways to control such a television without pointing the remote directly at the receiver. **Possible answer:** Aim the remote at an object in such a way that the reflected ray will hit the receiver. Use **Performance Assessment in the Science Classroom**, p. 93.

Reading Check

Answer an electric charge moving back and forth

Caption Answer

Figure 4 a transverse wave

Mini LAB

Investigating Electromagnetic Waves

Procedure

1. Point your **television remote control** in different directions and observe whether it will still control the **television**.
2. Place various materials in front of the infrared receiver on the television and observe whether the remote control still will operate the television. Some materials you might try are **glass, a book, your hand, paper, and a metal pan**.

Analysis

1. Was it necessary for the remote control to be pointing exactly toward the receiver to control the television? Explain.
2. Did the remote control continue to work when the various materials were placed between it and the receiver? Explain why or why not.

Figure 4 A vibrating electric charge creates an electromagnetic wave that travels outward in all directions from the charge. The wave in only one direction is shown here.

Determine whether an electromagnetic wave is a transverse wave or a compressional wave.

Changing Electric and Magnetic Fields A changing magnetic field creates a changing electric field. For example, in a transformer, changing electric current in the primary coil produces a changing magnetic field. This changing magnetic field then creates a changing electric field in the secondary coil that produces current in the coil. The reverse is also true: a changing electric field creates a changing magnetic field.

Making Electromagnetic Waves

Waves such as sound waves are produced when something vibrates. Electromagnetic waves also are produced when something vibrates—an electric charge that moves back and forth.

Reading Check What produces an electromagnetic wave?

When an electric charge vibrates, the electric field around it changes. Because the electric charge is in motion, it also has a magnetic field around it. This magnetic field also changes as the charge vibrates. As a result, the vibrating electric charge is surrounded by changing electric and magnetic fields.

How do the vibrating electric and magnetic fields around the charge become a wave that travels through space? The changing electric field around the charge creates a changing magnetic field. This changing magnetic field then creates a changing electric field. This process continues, with the magnetic and electric fields continually creating each other. These vibrating electric and magnetic fields are perpendicular to each other and travel outward from the moving charge, as shown in **Figure 4**. Because the electric and magnetic fields vibrate at right angles to the direction the wave travels, an electromagnetic wave is a transverse wave.

Visual Learning

Figure 4 The electromagnetic wave is shown in one direction to make it easier to visualize. In reality, a vibrating charge produces electromagnetic waves that travel in almost all directions. The wave shown here is vertically polarized: the electric field oscillates up and down, and the magnetic field oscillates right and left. In a horizontally polarized wave, the

electric field oscillates right and left and the magnetic field oscillates up and down. Ask students to describe how the amplitude, frequency, and wavelength of the electric and magnetic fields are related. **When the amplitude of the electric field is maximum, the amplitude of the magnetic field is maximum. The frequencies and wavelengths of the fields are the same.**

Properties of Electromagnetic Waves

All matter contains charged particles that are always in motion. As a result, all objects emit electromagnetic waves. The wavelengths of the emitted waves become shorter as the temperature of the material increases. As an electromagnetic wave moves, its electric and magnetic fields encounter objects. These vibrating fields can exert forces on charged particles and magnetic materials, causing them to move. For example, electromagnetic waves from the Sun cause electrons in your skin to vibrate and gain energy, as shown in **Figure 5**. The energy transferred by an electromagnetic wave is **radiant energy**. Radiant energy makes a fire feel warm and enables you to see.

Figure 5 As an electromagnetic wave strikes your skin, electrons in your skin gain energy from the vibrating electric and magnetic fields.

Applying Math Using Scientific Notation

THE SPEED OF LIGHT IN WATER The speed of light in water is 226,000 km/s. Write this number in scientific notation.

IDENTIFY known values and the unknown value

Identify the known values:

The speed of light in water is 226,000 km/s.

Identify the unknown value:

the number 226,000 written in scientific notation

SOLVE the problem

A number written in scientific notation has the form $M \times 10^N$. N is the number of places the decimal point in the number has to be moved so that the number M that results has only one digit to the left of the decimal point.

Write the number in scientific notation: $226,000. \times 10^N$

Move the decimal point so there is only one digit to its left: 2.26000×10^N

The decimal point was moved 5 places, so N equals 5: 2.26000×10^5

Delete remaining zeroes at the end of the number. 2.26×10^5

CHECK your answer

Add zeroes to the end of the number and move the decimal point in the opposite direction five places. The result should be the original number.

Practice Problems

Write the following numbers in scientific notation: 433; 812,000,000; 73,000,000,000; 84,500.

For more practice problems go to page 879, and visit Math Practice at fl.gpescience.com.

Quick Demo Waves

Materials coiled metal spring toy

Estimated Time 5–10 minutes

Procedure Have two volunteers hold each end of the spring on the floor. Demonstrate a transverse wave (a wave for which the medium moves at right angles to the direction the wave travels) by moving one end of the spring left and right. Demonstrate a longitudinal wave (a wave for which the medium moves along the same direction the wave travels) by holding both ends still, then gathering coils together and releasing them.

Applying Math

Math Standards

National: 1

Florida: MA.A.1.4.4

Answer to Practice Problem

$$433 = 4.33 \times 10^2$$

$$812,000,000 = 8.12 \times 10^8$$

$$73,000,000,000 = 7.3 \times 10^{10}$$

$$84,500 = 8.45 \times 10^4$$

Discussion

Scientific Notation Why is scientific notation useful when studying electromagnetic radiation? **Wavelength, frequency, and wave speed are often very large or very small numbers.**

Fun Fact

By 1800, many scientists suspected a relationship between electricity and magnetism. Then, in 1820, Hans Christian Oersted accidentally brought a wire carrying direct current near a compass needle while teaching class. The compass needle moved, demonstrating that the current-carrying wire was surrounded by a magnetic field.

Science Journal

Radiant Energy Warm objects emit more radiant energy than cool objects do. Have students investigate this topic and each write a paragraph summarizing what he/she learns. **All objects contain charged particles, such as electrons, that are always moving. These charged particles emit electromagnetic waves whose**

frequency depends on the frequency of vibration of the charges. As the temperature of the object increases, these charged particles move faster. Their frequency of vibration increases and the frequency of the electromagnetic radiation they emit increases. **L3** **LS** **Logical-Mathematical**

Activity

Drawing Waves To help students understand how frequency and wavelength are related, have one student draw a series of waves across the board, end to end, each having a similar wavelength. Have another student draw a series of waves with a much longer wavelength below the first set. The drawings should demonstrate that over the same distance, there are more waves with shorter wavelengths and fewer waves with longer wavelengths. **L2**

Visual-Spatial

Teacher FYI

Light History There is a rich scientific history leading to the idea that light has both particle and wave nature. In the fifth century B.C., the Pythagoreans thought streams of light were emitted by the eye. Newton formed a particle theory of light in the early eighteenth century, around the same time Huygens concluded that light was a wave. In 1905, Einstein proposed that electromagnetic waves can also behave as particles.

Reading Check

Answer 300,000 km/s in a vacuum

Reading Strategy

Target Supporting Evidence

As students read about wave speed, ask them to find evidence in the text that supports the following statement: The speed of electromagnetic waves depends on the material they travel through. Have them list the evidence and compare notes with a partner.

Table 1 Speed of Visible Light

Material	Speed (km/s)
Vacuum	300,000
Air	slightly less than 300,000
Water	226,000
Glass	200,000
Diamond	124,000

Wave Speed All electromagnetic waves travel at 300,000 km/s in the vacuum of space. Because light is an electromagnetic wave, the speed of electromagnetic waves in space is usually called the speed of light. The speed of light is nature's speed limit—nothing travels faster than the speed of light. In matter, the speed of electromagnetic waves depends on the material they travel through. Electromagnetic waves usually travel most slowly in solids and fastest in gases. **Table 1** lists the speed of visible light in various materials.

Reading Check What is the speed of light?

Wavelength and Frequency Like all waves, electromagnetic waves can be described by their wavelengths and frequencies. The wavelength of an electromagnetic wave is the distance from one crest to another, as shown in **Figure 6**.

The frequency of any wave is the number of wavelengths that pass a point in 1 s. The frequency of an electromagnetic wave also equals the frequency of the vibrating charge that produces the wave. This frequency is the number of vibrations, or back-and-forth movements, of the charge in one second. The frequency and wavelength of an electromagnetic wave are related. As the frequency increases, the wavelength becomes smaller.

Waves and Particles

The difference between a wave and a particle might seem obvious—a wave is a disturbance that carries energy, and a particle is a piece of matter. However, in reality, the difference is not so clear.

Waves as Particles In 1887, Heinrich Hertz found that by shining light on a metal, electrons were ejected from the metal.

Hertz found that whether or not electrons were ejected depended on the frequency of the light and not on the amplitude. Because the energy carried by a wave depends on its amplitude and not its frequency, this result was mysterious. Years later, Albert Einstein provided an explanation: electromagnetic waves can behave as a particle, called a **photon**, whose energy depends on the frequency of the waves.

Figure 6 The wavelength of an electromagnetic wave is the distance between the crests of the vibrating electric field or magnetic field.

Differentiated Instruction

Challenge Ask students to research the early discoveries of Hertz, Planck, and Einstein on the quantum theory, black body radiation, and the photoelectric effect. Have students create a timeline illustrating key concepts and experiments. **L3**

Behavioral Disorder Have students draw two waves on a piece of paper. Count the wavelengths in each wave. Discuss which wave has the highest frequency. For review, label resting point, amplitude, crest, trough, wavelength.

Particles of paint sprayed through two slits coat only the area behind the slits.

Electrons fired at two closely spaced openings form a wavelike interference pattern.

Water waves produce an interference pattern after passing through two openings.

Particles as Waves Because electromagnetic waves could behave as a particle, other scientists wondered whether matter could behave as a wave. If a beam of electrons were sprayed at two tiny slits, you might expect that the electrons would strike only the area behind the slits, like the spray paint in **Figure 7**. Instead, it was found that the electrons formed an interference pattern. This type of pattern is produced by waves when they pass through two slits and interfere with each other, as the water waves do in **Figure 7**. This experiment showed that electrons can behave like waves. It is now known that all particles, not only electrons, can behave like waves.

Figure 7 When electrons are sent through two narrow slits, they behave as a wave.

section 1 review

Summary

Making Electromagnetic Waves

- Moving electric charges are surrounded by an electric field and a magnetic field.
- A vibrating electric charge produces an electromagnetic wave.
- An electromagnetic wave consists of vibrating electric and magnetic fields that are perpendicular to each other and travel outward from the vibrating electric charge.

Properties of Electromagnetic Waves

- Electromagnetic waves carry radiant energy.
- In empty space, electromagnetic waves travel at 300,000 km/s, the speed of light.
- Electromagnetic waves travel more slowly in matter, with a speed that depends on the material.

Waves and Particles

- Electromagnetic waves can behave as particles that are called photons.
- In some circumstances, particles, such as electrons, can behave as waves.

Self Check

1. **Explain** why an electromagnetic wave is a transverse wave and not a compressional wave.
2. **Compare** the frequency of an electromagnetic wave with the frequency of the vibrating charge that produces the wave.
3. **Describe** how electromagnetic waves transfer radiant energy to matter.
4. **Explain** how an electromagnetic wave can travel through space that contains no matter.
5. **Think Critically** Suppose a moving electric charge were surrounded only by an electric field. Infer whether or not a vibrating electric charge would produce an electromagnetic wave.

Applying Math

6. **Calculate Time** How many minutes does it take an electromagnetic wave to travel 150,000,000 km?
7. **Use Scientific Notation** Calculate the distance an electromagnetic wave in space would travel in one day. Express your answer in scientific notation.

More Section Review fl.gpscience.com

SECTION 1 What are electromagnetic waves? 461

section 1 review

1. The vibrating electric and magnetic fields that create electromagnetic waves are perpendicular to the direction the wave travels. A compressional wave causes a disturbance that moves back and forth along the direction the wave travels.
2. They're equal.
3. by causing charged particles within objects to move
4. An electromagnetic wave is made of vibrating electric and magnetic fields that continually produce each other; matter is not needed for this to occur.
5. No, an electromagnetic wave would not be produced. Both a vibrating electric and magnetic field are needed to produce an electromagnetic wave that travels away from the vibrating charge.
6. $500 \text{ s} = 8.33 \text{ min}$
7. $2.592 \times 10^{10} \text{ km}$

MA.A.1.4.4, MA.B.2.4.2

Post Reading

Compare and Contrast Have students compare and contrast the behavior of waves and photons. Does the energy of a wave depend on its amplitude or frequency? What about a photon—on what does its energy depend? Have half the class share similarities and half the class note differences.

3 Assess

DAILY INTERVENTION

Check for Understanding

Logical-Mathematical Using two columns, chart the characteristics of sound waves and electromagnetic waves comparing and contrasting the properties of each.

Reteach

Seeing Waves Radio waves are long-wavelength, low-frequency electromagnetic waves, and gamma rays are short-wavelength, high-frequency waves. Have students model the relationship between wavelength and frequency of waves by vertically shaking a rope attached to a door handle. First, they can shake it with low frequency to see long wavelengths, then with higher frequency to see shorter wavelengths. **L2 ELL IS Kinesthetic**

Assessment

Portfolio Have students write several paragraphs that describe how electric and magnetic fields together form electromagnetic waves, and how these waves vary in frequency and wavelength. Use **Performance Assessment in the Science Classroom**, p. 159.

Tie to Prior Knowledge

X Rays Ask students if they have ever had an X-ray image taken by an X-ray technician. X rays are one form of electromagnetic waves that they will be studying in this section.

Activate Background Knowledge

Ask students to identify any familiar vocabulary words. Students will likely know *microwave* and *X ray*. Ask: What are these things and how do they work? Students may describe the words in terms of objects. Explain that a microwave oven uses microwaves and an X-ray machine uses X rays. Both are types of electromagnetic radiation.

Reading Guide

What You'll Learn

- **Describe** the waves in the different regions of the electromagnetic spectrum.
- **Compare** the properties of different electromagnetic waves.
- **Identify** uses for different types of electromagnetic waves.

Why It's Important

Waves in different regions of the electromagnetic spectrum are used every day in many ways.

Review Vocabulary

spectrum: a continuous sequence arranged by a particular property

New Vocabulary

- visible light
- radio wave
- microwave
- infrared wave
- ultraviolet wave
- X ray
- gamma ray

A Range of Frequencies

Electromagnetic waves can have a wide variety of frequencies. They might vibrate once each second or trillions of times each second. The entire range of electromagnetic wave frequencies is known as the electromagnetic spectrum, shown in **Figure 8**. Various portions of the electromagnetic spectrum interact with matter differently. As a result, they are given different names. The electromagnetic waves that humans can detect with their eyes, called **visible light**, are a small portion of the entire electromagnetic spectrum. However, various devices have been developed to detect the other frequencies. For example, the antenna of your radio detects radio waves.

Figure 8 Electromagnetic waves are described by different names, depending on their frequencies and wavelengths.

Figure 9 Microwave ovens use electromagnetic waves to heat food.

Radio Waves

Stop and look around you. Even though you can't see them, radio waves are moving everywhere you look. Some radio waves carry an audio signal from a radio station to a radio. However, even though these radio waves carry information that a radio uses to create sound, you can't hear radio waves. You hear a sound wave when the compressions and rarefactions the sound wave produces reach your ears. A radio wave does not produce compressions and rarefactions as it travels through air.

Microwaves Radio waves are low-frequency electromagnetic waves with wavelengths longer than about 1 mm. Radio waves with wavelengths of less than 30 cm are called **microwaves**. Microwaves with wavelengths of about 20 cm to 1 cm are widely used for communication, such as for cellular telephones and satellite signals. You are probably most familiar with microwaves because of their use in microwave ovens.

Reading Check What is the difference between a microwave and a radio wave?

Microwave ovens heat food when microwaves interact with water molecules in food, as shown in **Figure 9**. Each water molecule is positively charged on one side and negatively charged on the other side. The vibrating electric field inside a microwave oven causes water molecules in food to rotate back and forth billions of times each second. This rotation causes a type of friction between water molecules that generates thermal energy. It is the thermal energy produced by the interactions between the water molecules that causes your food to cook.

Radar Another use for radio waves is to find the position and movement of objects by a method called radar. Radar stands for **RA**dio **D**etecting **A**nd **R**anging. With radar, radio waves are transmitted toward an object. By measuring the time required for the waves to bounce off the object and return to a receiving antenna, the location of the object can be found. Law-enforcement officers use radar to measure how fast a vehicle is moving. Radar also is used for tracking the movement of aircraft, watercraft, and spacecraft.

Heating with Microwaves

Procedure

1. Obtain two small beakers or baby-food jars. Place 50 mL of dry sand in each. To one of the jars, add 20 mL of room-temperature water and stir well.
2. Record the temperature of the sand in each jar.
3. Together, microwave both jars of sand for 10 s and immediately record the temperature again.

Analysis

1. Compare the initial and final temperatures of the wet and dry sand.
2. Infer why there was a difference.

2 Teach

Make a Model

Water Waves Use a pan of water to model how altering the frequency of a vibrating object creates waves with different frequencies. [L1]

ELL **LS** Kinesthetic

Purpose Students observe how microwave ovens heat food. [L2]

ELL **LS** Kinesthetic

Materials microwave oven, two small beakers or baby food jars, dry sand, water, thermometer

Safety Precautions Do not over-heat the sand. [L1] [L2]

Analysis

1. Wet sand becomes much hotter than dry sand.
2. The microwaves increase the kinetic energy of the water molecules, which then transfer some of this energy to the sand.

Assessment

Process Ask students to infer why the inside of a microwave oven doesn't get hot. It is made of materials that don't absorb the energy transferred by microwaves. Use PASC, p. 89.

Reading Check

Answer Microwaves are radio waves with wavelengths of less than a meter.

Differentiated Instruction

Learning Disabled Draw a diagram on the board or on a long piece of paper similar to **Figure 8**. As each type of wave is discussed, tape examples of things that use that type of wave under the correct heading.

Visual Learning

Figure 9 Point out to students that water molecules are polar. The side with the hydrogen atoms has a slightly positive charge and the side with the oxygen atom has a slightly negative charge. Because of this polarity, the molecules tend to align themselves with an electric field. The changing electric field in microwaves causes the water molecules to rotate. [L2] **LS** Visual-Spatial

Fun Fact

While working with radar in the 1940s, Percy Spencer discovered that the candy in his pockets had melted. He also discovered that directing the radar toward popcorn caused the kernels to pop. From these observations, Spencer went on to develop the microwave oven.

Virtual Labs

Wavelength What is the electromagnetic spectrum?

Inquiry Lab

Investigating Infrared Photographs

Purpose To investigate the uses of infrared photography and conduct a simple investigation using an infrared photograph.

Possible Materials internet access, infrared photographs

Estimated Time 3–4 class sessions

Teaching Strategies

- Have students research uses of infrared photography and select one use to investigate in more detail. Examples: geology, vegetation health, environmental pollution, land use.
- Have students obtain a photograph related to their area of research, form a question and hypothesis that could be answered with the photo, and then answer the question.
- Students can present their findings to the class.
- U.S. Department of the Interior/U.S. Geological Survey has a fact sheet and a list of contacts. For more information go to fl.gpscience.com and follow the links to your chapter.

For additional inquiry activities, see *Science Inquiry Lab Manual*.

Figure 10 Magnetic resonance imaging technology uses radio waves as an alternative to X-ray imaging.

Magnetic Resonance Imaging (MRI) In the early 1980s, medical researchers developed a technique called magnetic resonance imaging, which uses radio waves to help diagnose illness. The patient lies inside a large cylinder, such as the one shown in **Figure 10**. Housed in the cylinder is a powerful magnet, a radio-wave emitter, and a radio-wave detector. Protons in hydrogen atoms in bones and soft tissue behave like magnets and align with the strong magnetic field. Energy from radio-waves causes some of the protons to flip their alignment. As the protons flip, they release radiant energy. A radio receiver detects this released energy. The amount of energy a proton releases depends on the type of tissue it is part of. The released energy detected by the radio receiver is used to create a map of the different tissues. A picture of the inside of the patient's body is produced painlessly.

Infrared Waves

Most of the warm air in a fireplace moves up the chimney, yet when you stand in front of a fireplace, you feel the warmth of the blazing fire. Why do you feel the heat? The warmth you feel is thermal energy transmitted to you by **infrared waves**, which are a type of electromagnetic wave with wavelengths between about one millimeter and 750 billionths of a meter.

You use infrared waves every day. A remote control emits infrared waves to control your television. A computer uses infrared waves to read CD-ROMs. In fact, every object emits infrared waves. Hotter objects emit more infrared waves than cooler objects emit. The wavelengths emitted also become shorter as the temperature increases. Infrared detectors can form images of objects from the infrared radiation they emit. Infrared sensors on satellites can produce infrared images that can help identify the vegetation over a region. **Figure 11** shows how cities appear different from surrounding vegetation in infrared satellite imagery.

Figure 11 Infrared images and visible light images can provide different types of information.

This visible light image of the region around San Francisco Bay in California was taken from an aircraft at an altitude of 20,000 m.

This infrared image of the same area was taken from a satellite. In this image, vegetation is red and buildings are gray.

Differentiated Instruction

Challenge Have students investigate other uses of infrared radiation, such as infrared spectroscopy and Forward-Looking Infrared Systems. Have them create informative posters conveying the various uses. **L3**

Science Journal

Imaging Safety Have students write short paragraphs in their Science Journals explaining why magnetic resonance imaging is safer than X rays. The radio waves used for magnetic resonance imaging have much lower energy than X rays, and they do not harm the body. **L2** **IS** **Linguistic**

Visible Light

Visible light is the range of electromagnetic waves that you can detect with your eyes. Light differs from radio waves and infrared waves only by its frequency and wavelength. Visible light has wavelengths around 750 billionths to 400 billionths of a meter. Your eyes contain substances that react differently to various wavelengths of visible light, so you see different colors. These colors range from long-wavelength red to short-wavelength blue. If all the colors are present, you see the light as white.

Ultraviolet Waves

Ultraviolet waves are electromagnetic waves with wavelengths from about 400 billionths to 10 billionths of a meter. Ultraviolet waves are energetic enough to enter skin cells. Overexposure to ultraviolet rays can cause skin damage and cancer. Most of the ultraviolet radiation that reaches Earth's surface is longer-wavelength UVA rays. The shorter-wavelength UVB rays cause sunburn, and both UVA and UVB rays can cause skin cancers and skin damage such as wrinkling. Although too much exposure to the Sun's ultraviolet waves is damaging, some exposure is necessary. Ultraviolet light striking the skin enables your body to make vitamin D, which is needed for healthy bones and teeth.

Useful UVs A useful property of ultraviolet waves is their ability to kill bacteria on objects such as food and medical supplies. When ultraviolet light enters a cell, it damages protein and DNA molecules. For some single-celled organisms, damage can mean death, which can be a benefit to human health. Ultraviolet waves are also useful because they make some materials fluoresce. Fluorescent materials absorb ultraviolet waves and reemit the energy as visible light. As shown in **Figure 12**, police detectives sometimes use fluorescent powder to show fingerprints when solving crimes.

Figure 12 The police detective in this picture is shining ultraviolet light on a fingerprint dusted with fluorescent powder.

CT Scans In certain situations, doctors will perform a computerized tomography (CT) scan on a patient instead of taking a traditional X ray. Research to find out more about CT scans. Compare and contrast CT scans with X rays. What are the advantages and disadvantages of a CT scan? Write a paragraph about your findings in your Science Journal.

Use Science Words

Word Meanings Ask students to find the meaning of the prefix infra- and explain why it is appropriate for describing infrared waves. *Infra-* means "below." It is appropriate because infrared waves have frequencies just below that of red light. **L2** **IS** **Linguistic**

CT Scans In both traditional X-ray imaging and CT (computerized tomography, also known as CAT, computerized axial tomography) scanning, X rays are passed through the body to provide an inside view. Traditional X-ray images are not appropriate for some purposes because they show only dense body parts. CT scans provide much clearer cross-sectional images made by rotating an X-ray beam around the patient. CT scans are more expensive.

Research Have students research specific uses for X rays and CT scans, and explain why each is best suited for that use.

Quick Demo

Visible Light Waves

Materials prism, light source, white screen

Estimated Time five minutes

Procedure Shine light onto a white screen. Refract light using a prism to show colors of light. Point out how each frequency refracted to a different degree with violet refracting the most and red the least.

LAB DEMONSTRATION

Purpose to demonstrate fluorescence **L2**

ELL **IS** **Kinesthetic**

Materials ultraviolet lamp; fluorescent rock kit or samples of calcite, fluorite, or opal; dry laundry detergent containing whiteners

Procedure In a darkened room, shine the UV

lamp on the rocks and laundry detergent. Turn the lamp on and off comparing the affect of UV vs. visible light. Shine the light on clothing to check for fluorescent whiteners.

WARNING: Be careful not to shine ultraviolet light in anyone's eyes.

Expected Outcome Students will observe the materials fluoresce.

Assessment

Why do the materials fluoresce? When ultraviolet light strikes the materials, the electrons absorb the energy, then reemit it as light at a lower frequency.

Use Science Words

Word Origins Have students find out where the word *ozone* comes from. The word *ozone* comes from the Greek word *ozein* meaning “to smell.” Point out that ozone can be formed when electricity or ultraviolet rays pass through oxygen. Its sharp smell can often be detected near electrical machinery or during a thunderstorm.

L2 **IS** Linguistic

Reading Check

Answer It absorbs harmful UV waves.

Content Background

Ozone in the stratosphere is necessary to protect life on Earth, but ozone near the ground is harmful. Ground-level ozone is the result of reactions between chemical pollutants mainly from factories and car exhaust. The reaction requires thermal energy and sunlight, so ozone pollution is most prevalent during the summer and in warm, sunny climates. Breathing in ozone can induce coughing and chest pain; prolonged exposure can cause permanent lung damage. It also damages plant foliage and reduces agricultural productivity.

Discussion

Upper Limit Ask students whether or not they believe there is an upper limit to the energy of electromagnetic waves. Gamma rays with energies greater than a trillion electron volts (TeV) have been detected. By comparison, photons of visible light have energies of only a few electron volts. Astronomers believe that gamma rays with energies a thousand times greater should be emitted by certain galaxies, and have built instruments to detect these high-energy gamma rays.

L3 **IS** Logical-Mathematical

Figure 13 The chlorine atoms in CFCs react with ozone high in the atmosphere. This reaction causes ozone molecules to break apart.

The Ozone Layer About 20 to 50 km above Earth's surface in the stratosphere is a region called the ozone layer. Ozone is a molecule composed of three oxygen atoms. It is continually being formed and destroyed by ultraviolet waves high in the atmosphere. The ozone layer is vital to life on Earth because it absorbs most of the Sun's harmful ultraviolet waves. However, over the past few decades, the amount of ozone in the ozone layer has decreased. Averaged globally, the decrease is about three percent, but it is greater at higher latitudes.

Reading Check Why is the ozone layer vital to life on Earth?

The decrease in ozone is caused by the presence of certain chemicals, such as CFCs, high in Earth's atmosphere. CFCs are chemicals called chlorofluorocarbons that have been widely used in air conditioners, refrigerators, and cleaning fluids. When CFC molecules reach the ozone layer, they react chemically with ozone molecules, as shown in **Figure 13**. One chlorine atom from a CFC molecule can break apart thousands of ozone molecules. As a result, many countries are reducing the use of CFCs and other ozone-depleting chemicals.

Reading Strategy

Sequence Have students sequence the steps in writing or with drawings that lead to ozone destruction in the atmosphere, beginning with the release of CFC molecules. Students can use **Figure 13** as a guide.

X Rays and Gamma Rays

The electromagnetic waves with the shortest wavelengths and highest frequencies are X rays and gamma rays. Both X rays and gamma rays are high-energy electromagnetic waves. **X rays** have wavelengths between about 10 billionths of a meter and 10 trillionths of a meter. Doctors and dentists use low doses of X rays to form images of internal organs, bones, and teeth, like the image shown in **Figure 14**. X rays also are used in airport screening devices to examine the contents of luggage.

Electromagnetic waves with wavelengths shorter than about 10 trillionths of a meter are **gamma rays**. These are the highest-energy electromagnetic waves and can penetrate through several centimeters of lead. Gamma rays are produced by processes that occur in atomic nuclei. Both X rays and gamma rays are used in a technique called radiation therapy to kill diseased cells in the human body. A beam of X rays or gamma rays can damage the biological molecules in living cells, causing both healthy and diseased cells to die. However, by carefully controlling the amount of X-ray or gamma-ray radiation received by the diseased area, the damage to healthy cells can be reduced.

Figure 14 Bones are more dense than surrounding tissues and absorb more X rays. The image of a bone on an X ray is the shadow cast by the bone as X rays pass through the soft tissue.

Post Reading

Panel Discussion Ask students to conduct further research on the ozone layer. Then have the class engage in a panel discussion about ozone depletion. What causes the problem? What steps are being taken to solve it? Should more action be taken?

3 Assess

DAILY INTERVENTION

Check for Understanding

Auditory-Musical Divide the class into six groups, assigning each one segment of the electromagnetic spectrum. Have groups write poems or rap songs highlighting key features of their segment.

Reteach

Wave Displays Divide the class into six groups. Ask each group to discuss and make a poster showing various properties and uses of one type of electromagnetic waves. Posters can be displayed in the classroom for reference. **L2 COOP LEARN**

Visual-Spatial

Assessment

Process Ask students to write paragraphs comparing and contrasting MRI and X-ray imaging. Both provide an inside view of a patient. MRI uses radio waves and is safer but more expensive. X-ray imaging uses potentially harmful X rays, but is less expensive. MRI provides clearer images. Use **Performance Assessment** in the Science Classroom, p. 157.

section 2 review

Summary

Radio Waves and Infrared Waves

- Radio waves are electromagnetic waves with wavelengths longer than about 1 mm.
- Microwaves are radio waves with wavelengths between about 30 cm and 1 mm.
- Infrared waves have wavelengths between about 1 mm and 750 billionths of a meter.

Visible Light and Ultraviolet Waves

- Visible light waves have wavelengths between about 750 and 400 billionths of a meter.
- Ultraviolet waves have wavelengths between about 400 and 10 billionths of a meter.
- Most of the harmful ultraviolet waves emitted by the Sun are absorbed by the ozone layer.

X Rays and Gamma Rays

- X rays and gamma rays are the most energetic electromagnetic waves.
- Gamma rays have wavelengths less than 10 trillionths of a meter and are produced in the nuclei of atoms.

Self Check

1. **Explain** A mug of water is heated in a microwave oven. Explain why the water gets hotter than the mug.
2. **Describe** why you can see visible light waves but not other electromagnetic waves.
3. **List** the beneficial effects and the harmful effects of human exposure to ultraviolet rays.
4. **Identify** three objects in a home that produce electromagnetic waves and describe how the electromagnetic waves are used.
5. **Think Critically** What could an infrared image of their house reveal to homeowners?

Applying Math

6. **Use Scientific Notation** Express the range of wavelengths corresponding to visible light, ultraviolet waves, and X rays in scientific notation.
7. **Convert Units** A nanometer, abbreviated nm, equals one billionth of a meter, or 10^{-9} m. Express the range of wavelengths corresponding to visible light, ultraviolet waves, and X rays in nanometers.

SECTION 2 The Electromagnetic Spectrum 467

section 2 review

1. The molecules of which the mug is made do not absorb the energy transferred by microwaves; water molecules do absorb microwave energy.
2. Human eyes contain chemical compounds that absorb the energy carried by visible light waves.
3. beneficial effects: production of Vitamin D in human body; harmful affects: damage protein and DNA molecules in cells, can damage skin and cause skin cancer
4. answers will vary
5. Possible answer: where thermal energy is escaping from the house, and where insulation would be

- needed to reduce energy loss
6. visible light = $7.5 \text{ to } 4.0 \times 10^{-7}$ m, ultraviolet = $40 \text{ to } 1.0 \times 10^{-8}$ m, X rays = 1.0×10^{-8} m to 1.0×10^{-11} m
7. visible light = 750 to 400 nm, ultraviolet = 400 to 10 nm, X rays = 10 to 0.01 nm

MA.A.1.4.4, MA.B.1.4.2

Video Lab available for this Lab.

Real-World Problem

Purpose Students learn how the shape of a satellite dish affects reception. **L2** **ELL**

Kinesthetic

Process Skills observe and infer, communicate, compare and contrast, recognize cause and effect, make models

Time Required 30 minutes

Alternate Materials Any small parabolic object can be used.

Procedure

Teaching Strategy For accurate comparison, be sure students have the flashlight at the same distance from the receptor for all measurements.

Conclude and Apply

1. The light on the flat surface is spread out, but the light on the curved surface is mostly an intense spot in the middle.
2. The light from the flashlight spreads out as it leaves the flashlight. When it hits a flat surface, this light remains spread out. When it hits a curved surface, the light is reflected to the center, forming the intense spot.
3. This activity uses visible light as a model for the microwaves used in satellite communication. A curved satellite dish focuses the signal so that reception is much better.

LAB

The Shape of Satellite Dishes

Communications satellites transmit signals with a narrow beam pointed toward a particular area of Earth. To detect this signal, receivers are typically large, parabolic dishes.

Real-World Problem

How does the shape of a satellite dish improve reception?

Goals

- **Make** a model of a satellite reflecting dish.
- **Observe** how the shape of the dish affects reception.

Materials

flashlight	small bowl
several books	*large, metal spoon
aluminum foil	*Alternate materials

Safety Precautions

Procedure

1. Cover one side of a book with aluminum foil. Be careful not to wrinkle the foil.
2. Line the inside of the bowl with foil, also keeping it as smooth as possible.
3. Place some of the books on a table. Put the flashlight on top of the books so that its beam of light will shine several centimeters above and across the table.
4. Hold the foil-covered book on its side at a right angle to the top of the table. The foil-covered side should face the beam of light.
5. **Observe** the intensity of the light on the foil.

6. Repeat steps 4 and 5, replacing the foil-covered book with the bowl.

Conclude and Apply

1. **Compare** the brightness of the light reflected from the two surfaces.
2. **Explain** why the light you see from the curved surface is brighter.
3. **Infer** why bowl-shaped dishes are used to receive signals from satellites.

Communicating Your Data

Compare your conclusions with those of other students in your class. For more help, refer to the **Science Skill Handbook**.

Communicating Your Data

Have students use a computer graphics program to prepare sketches of the models they created in this activity. The sketches should show how the light is reflected directly back from a flat surface, but is reflected toward the center of a curved surface. Have students compare their sketches.

Assessment

Oral After students have completed the activity, ask them to explain why focusing a satellite signal is important. **Focusing increases the intensity of the satellite signal.** Use **Performance Assessment in the Science Classroom**, p. 89.

Radio Communication

Reading Guide

What You'll Learn

- **Explain** how modulating carrier waves enables information to be transmitted by radio waves.
- **Distinguish** between amplitude modulation and frequency modulation.
- **Identify** various ways of communicating using radio waves.

Why It's Important

Every day, you use radio waves to communicate.

Review Vocabulary

modulate: to vary the amplitude or frequency of a wave to transmit information

New Vocabulary

- carrier wave
- cathode-ray tube
- transceiver
- Global Positioning System (GPS)

Radio Transmission

When you listen to the radio, you hear music and words that are produced at a distant location. The music and words are sent to your radio by radio waves. The metal antenna of your radio detects radio waves. As the electromagnetic waves pass by your radio's antenna, the electrons in the metal vibrate, as shown in **Figure 15**. These vibrating electrons produce a changing electric current that contains the information about the music and words. An amplifier boosts the current and sends it to speakers, causing them to vibrate. The vibrating speakers create sound waves that travel to your ears. Your brain interprets these sound waves as music and words.

Dividing the Radio Spectrum Each radio station is assigned to broadcast at one particular radio frequency. Turning the tuning knob on your radio allows you to select a particular frequency to listen to. The specific frequency of the electromagnetic wave that a radio station is assigned is called the **carrier wave**.

The radio station must do more than simply transmit a carrier wave. The station has to send information about the sounds that you are to receive. This information is sent by modifying the carrier wave. The carrier wave is modified to carry information in one of two ways, as shown in **Figure 16**.

Figure 15 Radio waves exert a force on the electrons in an antenna, causing the electrons to vibrate.

SECTION 3 Radio Communication 469

1 Motivate

An editable Microsoft® PowerPoint® presentation is available on Interactive Chalkboard CD-ROM.

Bellringer

Section Focus Transparencies also are available on the Interactive Chalkboard CD-ROM.

L2 ELL

Section Focus Transparency Could it be a growth spurt?

The Global Positioning System (GPS) uses electromagnetic waves and satellites to determine locations and measurements on Earth. For example, one group of scientists found that Mount Everest is actually 8,850 m (29,035 feet) tall, 2.1 m higher than the figure accepted since 1954. This man is demonstrating another use of the GPS. By connecting a receiver to a computer, he is able to map his location.

1. Name some ways people might use the GPS.
2. Could the GPS function using sound waves? Explain.

L2

Reading Preview

Tie to Prior Knowledge

Communication Ask students to name different forms of electronic communication. They might mention radio, television, telephone, or the Internet. Tell them that much communication relies on the use of radio waves.

Make Connections Tell students to imagine they are lost in the woods. How could they find their way out? After allowing discussion, explain that technology exists that allows the user to pinpoint his or her exact location. The technology is called the Global Positioning System (GPS). Ask them to predict how they think it may work.

Use an Analogy

Boat's Sail Having a larger sail on a boat increases the amount of wind you catch, so the boat moves faster. Similarly, lengthening a radio's antenna frequently improves reception because a larger area of the electromagnetic field is intercepted.

Quick Demo

Favorite Frequencies

Materials AM/FM radio

Estimated Time ten minutes

Procedure Bring a radio to class and have students tune it to AM and FM stations. Stress that radios are tuned in by the frequency of the carrier wave. List students' favorite radio stations on the board in order of increasing frequency. [L2]

Auditory-Musical

IDENTIFYING

Misconceptions

Wave Frequency Students might assume that AM stations broadcast with higher-frequency carrier waves than FM stations. For example, a station at 620 AM might seem to have a higher frequency than a station at 98 FM because 620 is greater than 98. Explain that the AM frequencies are in thousands of vibrations per second, while the FM frequencies are in millions of vibrations per second.

Carrier wave

Signal

Amplitude modulation

Frequency modulation

Figure 16 A carrier wave broadcast by a radio station can be altered in one of two ways to transmit a signal: amplitude modulation (AM) or frequency modulation (FM).

AM Radio An AM radio station broadcasts information by varying the amplitude of the carrier wave, as shown in **Figure 16**. Your radio detects the variations in amplitude of the carrier wave and produces a changing electric current from these variations. The changing electric current makes the speaker vibrate. AM carrier-wave frequencies range from 540,000 to 1,600,000 Hz.

FM Radio Electronic signals are transmitted by FM radio stations by varying the frequency of the carrier wave, as in **Figure 16**. Your radio detects the changes in frequency of the carrier wave. Because the strength of the FM waves is kept fixed, FM signals tend to be more clear than AM signals. FM carrier frequencies range from 88 million to 108 million Hz. This is much higher than AM frequencies, as shown in **Figure 17**. **Figure 18** shows how radio signals are broadcast.

Figure 17 Cell phones, TVs, and radios broadcast at frequencies that range from more than 500,000 Hz to almost 1 billion Hz.

470 CHAPTER 15 Electromagnetic Radiation

Differentiated Instruction

English-Language Learners To help students understand the meaning of *frequency* and *hertz*, have a student draw high-frequency waves on one end of the board and low-frequency waves on the other. When you list radio stations, write each radio station near the appropriate picture. Point to the pictures often as you use the terms *frequency*, *vibrations per second*, and *hertz*. [L1] [ELL]

Curriculum Connection

Math The frequencies of AM radio stations are in kilohertz and those of FM stations are in megahertz. Have students use the equation $\text{wavelength} = c/f$ to determine the wavelengths of the signals transmitted by local radio stations: ($c = 300,000,000 \text{ m/s}$) Possible answer: For 98.6 FM, the wavelength is $\lambda = 300,000,000 \text{ m/s} / 98,600,000 \text{ Hz} = 3.04 \text{ m}$ [L3] [LS] **Logical-Mathematical**

Figure 18

You flick a switch, turn the dial, and music from your favorite radio station fills the room. Although it seems like magic, sounds are transmitted over great distances by converting sound waves to electromagnetic waves and back again, as shown here.

A At the radio station, musical instruments and voices create sound waves by causing air molecules to vibrate. Microphones convert these sound waves to a varying electric current, or electronic signal.

B This signal then is added to the station's carrier wave. If the station is an AM station, the electronic signal modifies the amplitude of the carrier wave. If the station is an FM station, the electronic signal modifies the frequency of the carrier wave.

C The modified carrier wave is used to vibrate electrons in the station's antenna. These vibrating electrons create a radio wave that travels out in all directions at the speed of light.

D The radio wave from the station makes electrons in your radio's antenna vibrate. This creates an electric current. If your radio is tuned to the station's frequency, the carrier wave is removed from the original electronic signal. This signal then makes the radio's speaker vibrate, creating sound waves that you hear as music.

SECTION 3 Radio Communication 471

Visualizing Radio Broadcasts

Have students examine the pictures and read the captions. Then ask the following questions.

Compare and contrast how electromagnetic waves are modified to create AM and FM radio signals. Both signals are made by modifying electromagnetic waves and adding them to a carrier wave. The amplitude of the AM carrier wave is modified. The frequency of the FM carrier wave is modified.

Explain the roles of antennas in radio transmission and reception. In transmission, electrons in an antenna are caused to vibrate, sending the electromagnetic wave out in all directions at the speed of light. In reception, the electromagnetic wave makes electrons in an antenna vibrate. The vibrating electrons in the antenna form an electric current that is detected by a receiver.

Activity

Wave Skit Have students write and perform a skit about the life of a radio wave from birth (original sound wave) to death (final conversion back to a sound wave and then dampened). L2

L5 Kinesthetic

Fun Fact

Radio had only been in use for a few years when the *Titanic* sent its distress calls in 1912. Although radio is credited in aiding *Titanic's* survivors, it was the lack of radio communication with the ship *Californian* that sealed the fate of many who perished.

Reading Strategy

Ask Questions After students have read about radio broadcasts, ask them to think of questions they might have for a radio disc jockey. Tell them to write the questions in the form of an interview. If possible, invite a local disc jockey to the class for a group interview.

Differentiated Instruction

Challenge Ask students to find out how radio frequencies are assigned in the United States and how the Federal Communications Commission (FCC) regulates the industry. Have them present their findings to the class. L3

Use an Analogy

Jigsaw Puzzle The tiny rectangles or lines on a television or computer screen form a complete image the same way pieces of a jigsaw puzzle do. Individually the pieces seem meaningless, but when put together they form a picture.

Astronomers Learning about objects in distant space requires observing the universe with the entire range of electromagnetic waves. The *Compton Gamma Ray Observatory*, for example, detected gamma rays to look for pulsars at the centers of galaxies. The *Chandra X-ray Observatory* detects X rays to search for binary stars and black holes. The *Hubble Space Telescope* detects electromagnetic waves from ultraviolet to infrared to look at stars and galaxies.

Research Have students investigate what an astronomer does during a typical work day and the type of challenges they face. Present findings to the class.

Teacher FYI

Display Options To avoid large cathode-ray tubes, flat-screen televisions and the displays on laptop computers use liquid crystal displays or gas-plasma displays.

✓ Reading Check

Answer a sealed vacuum tube in which one or more beams of electrons are produced

Astronomers Do you ever look up at the stars at night and wonder how they were formed? With so many stars and so many galaxies, life might be possible on other planets. Research ways that astronomers use electromagnetic waves to investigate the universe. Choose one project astronomers currently are working on that interests you, and write about it in your Science Journal. Discuss the benefits of a career in astronomy.

Figure 19 Cathode-ray tubes produce the images you see on television. The inside surface of a television screen is covered by groups of spots that glow red, green, or blue when struck by an electron beam.

Television

What would people hundreds of years ago have thought if they had seen a television? Televisions might seem like magic, but not if you know how they work. Television and radio transmissions are similar. At the television station, sounds and images are changed into electronic signals. These signals are broadcast by carrier waves. The audio part of television is sent by FM radio waves. Information about the color and brightness is sent at the same time by AM signals.

Cathode-Ray Tubes In many television sets, images are displayed on a cathode-ray tube (CRT), as shown in **Figure 19**. A **cathode-ray tube** is a sealed vacuum tube in which one or more beams of electrons are produced. The CRT in a color TV produces three electron beams that are focused by a magnetic field and strike a coated screen. The screen is speckled with more than 100,000 rectangular spots that are of three types. One type glows red, another glows green, and the third type glows blue when electrons strike it. The spots are grouped together, with a red, green, and blue spot in each group.

An image is created when the three electron beams of the CRT sweep back and forth across the screen. Each electron beam controls the brightness of each type of spot, according to the information in the video signal from the TV station. By varying the brightness of each spot in a group, the three spots together can form any color so that you see a full-color image.

✓ **Reading Check** What is a cathode-ray tube?

472 CHAPTER 15 Electromagnetic Radiation

Cultural Diversity

Television As a young boy, Kenjito Takayanagi was a slow learner in school, but hard work enabled him to overcome his difficulties. In 1926, he transmitted the first television signal in Japan. Today he is honored as the founder of Japanese television. Have students make a class time line showing this and other contributions to the invention of television.

Visual Learning

Figure 19 The tiny rectangular spots on a television screen are colored red, green, and blue because these are the primary colors of light. Our eyes combine these into different colors, depending on the intensity of each rectangle. To demonstrate this idea, allow students to experiment with additive color filters or paddles. **L2** **LS** **Visual-Spatial**

Telephones

Until about 1950, human operators were needed to connect telephone calls between people. Just 20 years ago, you never would have seen someone walking down the street talking on a telephone. Today, cell phones are seen everywhere. When you speak into a telephone, a microphone converts sound waves into an electrical signal. In cell phones, this current is used to create radio waves that are transmitted to and from a microwave tower, as shown in **Figure 20**. A cell phone uses one radio signal for sending information to a tower at a base station. It uses another signal for receiving information from the base station. The base stations are several kilometers apart. The area each one covers is called a cell. If you move from one cell to another while using a cell phone, an automated control station transfers your signal to the new cell.

 **Reading Check** What are the cells in a cell-phone system?

Cordless Telephones Like a cellular telephone, a cordless telephone is a transceiver. A **transceiver** transmits one radio signal and receives another radio signal from a base unit. Having two signals at different frequencies allows you to talk and listen at the same time. Cordless telephones work much like cell phones. With a cordless telephone, however, you must be close to the base unit. Another drawback is that when someone nearby is using a cordless telephone, you could hear that conversation on your phone if the frequencies match. For this reason, many cordless phones have a channel button. This allows you to switch your call to another frequency.

Pagers Another method of transmitting signals is a pager, which allows messages to be sent to a small radio receiver. A caller leaves a message at a central terminal by entering a call-back number through a telephone keypad or by entering a text message from a computer. At the terminal, the message is changed into an electronic signal and transmitted by radio waves. Each pager is given a unique number for identification. This identification number is sent along with the message. Your pager receives all messages that are transmitted in the area at its assigned frequency. However, your pager responds only to messages with its particular identification number. Newer pagers can send data as well as receive them.

Figure 20 The antenna at the top of a microwave tower receives signals from nearby cell phones.

Determine whether any microwave towers are located near your school or home. Describe their locations.

ScienceOnline

Topic: Radio Wave Technology

Visit fl.gpescience.com for Web links to information about advances in radio-wave technology.

Activity List the advances you find, and write about the significance of each one in your Science Journal.

Discussion

Cell Limit Why is there a limit to the number of people who can talk on cell phones in a particular cell at the same time? Each phone uses a different frequency of electromagnetic waves. If all of the assigned frequencies are being used, no other phones can be used at that time. [L2]

 Logical-Mathematical

Caption Answer

Figure 20 Students should be encouraged to look for microwave towers on both freestanding towers and on other tall objects, such as buildings or water towers.

Discussion

Building Block Why is it difficult to talk on a cell phone if you are inside a metal building? The metal reflects the incoming and outgoing microwaves. [L2]

 Logical-Mathematical

Reading Check

Answer the area that can receive signals from a base station

Science Journal

Telephones of the Future Technology associated with telephones is changing rapidly, and the difference between computers and telecommunication devices is becoming less distinct. Have students write in their Science Journals descriptions of what they think telephones will be like in ten years. [L2]    Linguistic

Use Science Words

Word Origin The word *satellite* has many meanings. Ask students to look up the origin of the word *satellite* and list various types of satellites. For each one, they should describe why the word satellite is an appropriate term. *Satellite* comes from the Latin word *satelles* meaning “attendant.” Possible types: moons, satellite countries

Activity

GEO v. GPS Most communication satellites follow a geostationary equatorial orbit (GEO), also called a geosynchronous orbit. This is not the case with satellites for the Global Positioning System (GPS). Have students research the difference between a GEO and a GPS orbit. In a GEO, the satellite orbits Earth directly above the equator once every 24 hours, so that it is always above the same point on the equator. It maintains an altitude of about 35,800 km. In contrast, each of the 24 GPS satellites follows a different, circular orbit, circling Earth every 12 hours at an altitude of about 20,000 km.

  **Linguistic**

Figure 21 Communications satellites, like the one shown here, use solar panels to provide the electrical energy they need to communicate with receivers on Earth. The solar panels are the structures on either side of the central body of the satellite.

Communications Satellites

Since satellites were first developed, thousands have been launched into Earth's orbit. Many of these, like the one in **Figure 21**, are used for communication. A station broadcasts a high-frequency microwave signal to the satellite. The satellite receives the signal, amplifies it, and transmits it to a particular region on Earth. To avoid interference, the frequency broadcast by the satellite is different from the frequency broadcast from Earth.

Satellite Telephone Systems If you have a mobile telephone, you can make a phone call when sailing across the ocean. To make a call on a mobile telephone, the telephone transmits radio waves directly to a satellite. The satellite relays the signal to a ground station, and the call is passed on to the telephone network. Satellite links work well for one-way transmissions, but two-way communications can have an annoying delay caused by the large distance the signals must travel to and from the satellite.

Television Satellites The satellite-reception dishes that you sometimes see in yards or attached to houses are receivers for television satellite signals. Satellite television is used as an alternative to ground-based transmission. Television satellites use microwaves rather than the longer-wavelength radio waves used for normal television broadcasts. Short-wavelength microwaves travel more easily through the atmosphere. The ground receiver dishes are rounded to help focus the microwaves onto an antenna.

 **Science Online**

Topic: Satellite Communication

Visit fl.gpscience.com for Web links to information about ways satellites are used for communication.

Activity Write a paragraph describing the advantages of placing a communications satellite in a geosynchronous orbit. Include a diagram.

Active Reading

Metacognition Journal In this strategy, each student analyzes his or her own thought processes. Have students divide the paper in half. On the left, have them record what they have learned about a topic. On the right, have them record the reason they learned it. Have students write a Metacognition Journal about electromagnetic waves and communication.

The Global Positioning System

Getting lost while hiking is not uncommon, but if you are carrying a Global Positioning System receiver, this is much less likely to happen. The **Global Positioning System (GPS)** is a system of satellites, ground monitoring stations, and receivers that determine a person's or object's exact location at or above Earth's surface. The 24 satellites necessary for 24-hour, around-the-world coverage became fully operational in 1995. GPS satellites are owned and operated by the United States Department of Defense, but the microwave signals they send out can be used by anyone. As shown in **Figure 22**, signals from four satellites are needed to determine the location of an object using a GPS receiver. Today, GPS receivers are used in airplanes, ships, cars, and even by hikers.

Figure 22 A GPS receiver uses signals from orbiting satellites to determine the receiver's location.

section 3 review

Summary

Radio Transmission

- Radio stations transmit electromagnetic waves that receivers convert to sound waves.
- Each AM radio station is assigned a carrier-wave frequency and varies the amplitude of the carrier waves to transmit a signal.
- Each FM radio station is assigned a carrier-wave frequency and varies the frequency of the carrier waves to transmit a signal.

Television

- TV sets use cathode-ray tubes to convert electronic signals from TV stations into both sounds and images.

Telephones

- Telephones contain transceivers that convert sound waves into electrical signals and also convert electrical signals into sound waves.
- Wires, microwave towers, and satellites are used to transmit and receive telephone signals.

Global Positioning System (GPS)

- The GPS uses a system of satellites to determine a person's or object's exact position.

Self Check

1. **Explain** the difference between AM and FM radio. Make a sketch of how a carrier wave is modulated in AM and FM radio.
2. **Define** a cathode-ray tube, and explain how it is used in a television.
3. **Describe** what happens if you are talking on a cell phone while riding in a car and you travel from one cell to another cell.
4. **Explain** some of the uses of the Global Positioning System. Why might emergency vehicles be equipped with GPS receivers?
5. **Think Critically** Why do cordless telephones stop working if you move too far from the base unit?

Applying Math

6. **Calculate a Ratio** A group of red, green, and blue spots on a TV screen is a pixel. A standard TV has 460 pixels horizontally and 360 pixels vertically. A high-definition TV has 1,920 horizontal and 1,080 vertical pixels. What is the ratio of the number of pixels in a high-definition TV to the number in a standard TV?

section 3 review

1. For AM, amplitude is modulated. For FM, frequency is modulated. Check students' sketches.
2. A sealed vacuum tube in which beams of electrons are produced. The electron beams hit dots on a coated screen, causing them to glow.
3. A central controller transfers your signal to the base station in the new cell.
4. GPS is used by hikers, airplanes, ships, cars, and others to identify their location on Earth. Emergency vehicles have GPS receivers to help them find places quickly.
5. The radio waves broadcast by the base unit become too weak for the handset to detect.
6. 12.5 to 1

Post Reading

Supplemental Related Resources Obtain several manuals for televisions, portable phones, radios, or pagers. Have students scan through the booklets. Ask them to point out concepts in the manuals that they now understand, having read this section. Possible concepts might include AM and FM frequencies.

3 Assess

DAILY INTERVENTION

Check for Understanding

Visual-Spatial In pairs or small groups, have students create diagrams that illustrate the steps required for a radio, television, telephone, or satellite to transmit a message.

Reteach

How It Works Bring a radio or television into your classroom. Have students demonstrate the use of each device with proper physics explanations. They should include explanations about how the radio waves are picked up and what happens when you change the channel. **L2 AS Kinesthetic**

Assessment

Performance Have students work in pairs to make posters that show how one form of radio communication described in this section works. Posters can be displayed in the classroom to help students remember what they have studied. Use **Performance Assessment in the Science Classroom**, p. 145. **L2**

COOP LEARN AS Visual-Spatial

Real-World Problem

Purpose

Internet Students will use Internet sites that can be accessed through fl.gpescience.com. They will investigate AM and FM radio station transmission frequencies and ranges.

Non-Internet Sources Contact the Federal Communications Commission (FCC) for information about station transmission frequencies and ranges.

Process Skills follow a procedure, compare and contrast, infer

Time Required two days

Make a Plan

Preparation Access fl.gpescience.com to run through the steps that the students will follow.

Non-Internet Sources Organize FCC information about local radio stations by frequency and range.

Follow Your Plan

Teaching Strategy Remind students that AM stations broadcast at a lower frequency. These signals reflect off the ionosphere, providing a greater range. FM signals must travel by line of sight, so their range is less.

Radio Frequencies

Real-World Problem

The signals from many radio stations broadcasting at different frequencies are hitting your radio's antenna at the same time. When you tune to your favorite station, the electronics inside your radio amplify the signal at the frequency broadcast by the station. The signal from your favorite station is broadcast from a transmission site that may be several miles away.

You may have noticed that if you're listening to a radio station while driving in a car, sometimes the station gets fuzzy and you hear another station at the same time. Sometimes you lose the station completely. How far can you drive before this happens? Does the distance vary depending on the station you listen to? What are the ranges of radio stations? Form a hypothesis about how far you think a radio station can transmit. Which type of signal, AM or FM, has a greater range? Form a hypothesis about the range of your favorite radio station.

Make a Plan

1. **Research** what frequencies are used by AM and FM radio stations in your area and other areas around the country.
2. **Determine** these stations' broadcast locations.
3. **Determine** the broadcast range of radio stations in your area.
4. **Observe** how frequencies differ. What is the maximum difference between frequencies for FM stations in your area? AM stations?

Goals

- **Research** which frequencies are used by different radio stations.
- **Observe** the reception of your favorite radio station.
- **Make** a chart of your findings and communicate them to other students.

Data Source

Internet Lab

Visit fl.gpescience.com for more information on radio frequencies, different frequencies of radio stations around the country, and the ranges of AM and FM broadcasts.

Alternative Inquiry Lab

Student Investigation To make this Lab an Inquiry Lab, have students design a way to compare the reception of local AM and FM stations under various conditions, such as day/night or clear/cloudy.

Using Scientific Methods

Follow Your Plan

1. **Make** sure your teacher approves your plan before you start.
2. Visit the Web site shown below for links to different radio stations.
3. **Compare** the different frequencies of the stations and the locations of the broadcasts.
4. **Determine** the range of radio stations in your area and the power of their broadcast signals in watts.
5. **Record** your data in your Science Journal.

Analyze Your Data

1. **Make** a map of the radio stations in your area. Do the ranges of AM stations differ from those of FM stations?
2. **Make** a map of different radio stations around the country. Do you see any patterns in the frequencies for stations that are located near each other?
3. **Write** a description that compares how close the frequencies of AM stations are and how close the frequencies of FM stations are. Also compare the power of their broadcast signals and their ranges.
4. **Share** your data by posting it at the Web site shown below.

Conclude and Apply

1. **Compare** your findings with those of your classmates and other data that are posted at the Web site shown below. Do all AM stations and FM stations have different ranges?
2. **Observe** your map of the country. How close can stations with similar frequencies be? Do AM and FM stations appear to be different in this respect?
3. **Infer** The power of a broadcast signal also determines its range. How does the power (wattage) of the signals affect your analysis of your data?

Communicating Your Data

Find this lab using the Web site below. Post your data in the table provided. **Compare** your data with those of other students. Then combine your data with theirs and make a map for your class that shows all of the data.

Internet Lab
fl.gpscience.com

Analyze Your Data

1. AM stations have longer ranges than FM stations. AM signals are reflected by the ionosphere, which enables the signals to travel farther. The higher frequency FM signals are not reflected.
2. If two stations' transmitters are close to each other, their stations' frequencies will not be the same.
3. AM stations are spaced no closer than 10 kHz. FM stations are spaced no closer than 200 kHz.
4. Students can compare radio stations' ranges and frequencies in different locations around the country.

Conclude and Apply

1. AM stations and FM stations have different ranges. Broadcast range depends on a station's transmitter power.
2. Station transmitters with similar frequencies cannot be very close together because their signals would interfere with one another. AM stations differ from FM stations in how close their transmitters can be, because AM stations have a greater broadcast range than FM stations.
3. Students should use information about signal power and frequency to determine the ranges of radio stations.

Assessment

Performance Show radio station transmitter locations on a map of your area. Have students draw each station's range on the map to understand how reception and interference can affect the ability to receive a station's signal. Use **Performance Assessment in the Science Classroom**, p. 127.

Communicating Your Data

Use a spreadsheet program to collect information about radio stations. Include the station's call letters, locations of transmitters, frequency, and power.

Content Background

By the nineteenth century, it was widely believed that because light was a wave, it required a medium in which to travel, just as sound travels through air. The medium was called the ether, and was believed to be stationary. As a result, the ether provided an absolute reference system to which measurements in all other reference systems could be compared.

Several attempts were made to detect the ether, but failed. In 1887, Albert Michelson and Edward Morley attempted to measure the motion of Earth through the ether. To their surprise, they found no effects on the speed of light due to Earth's motion through the ether.

Einstein's paper on the special theory of relativity appeared in 1905. It postulated that physical laws have the same form and that the speed of light is a constant in any reference frame that is not accelerating. It was soon realized that the special theory could account for the results of the Michelson-Morley experiment, which was now seen as proving that the ether did not exist.

Discussion

Resisting Change Why are new theories often met with resistance? *Possible answer: When theories are first proposed, they may not be supported by enough experimental evidence to convince people of their validity.*

Historical Significance

Additional Ideas Einstein's theory of special relativity led to the idea that matter and energy are equivalent ($E=mc^2$). The theory also provides a more accurate description of phenomena involving objects moving near the speed of light than was provided by Newton's laws of motion.

Riding a Beam of Light

Einstein and the Special Theory of Relativity

Catch a Wave

At age 16, Albert Einstein wondered, "What would it be like to ride a beam of light?" He imagined what might happen if he turned on a flashlight while riding a light beam. Because the flashlight already would be traveling at the speed of light, would light from the flashlight travel at twice the speed of light?

What's so special?

Einstein thought about this problem, and in 1905, he published the special theory of relativity. This theory states that the speed of light will be the same when measured by any observer that moves with a constant speed. The measured speed of light will not depend on the speed of the observer or on how fast the source of light is moving. Einstein answered the question he had

asked himself when he was 16. He found the universal speed limit that can't be broken.

It Doesn't Add Up

According to Einstein, electromagnetic waves such as light waves behave very differently from other waves. For example, sound waves from the siren of an ambulance moving toward you move faster than they would if the ambulance were not moving. The speed of the ambulance adds to the speed of the sound waves. However, for light waves, the speed of a light source doesn't add to the speed of light.

Very Strange, but True

Einstein's special theory of relativity makes other strange predictions. According to this theory, no object can travel faster than the speed of light. Another prediction is that the measured length of a moving object is shorter than when the object is at rest. Also, moving clocks should run more slowly than when they are at rest. These predictions have been confirmed by experiments. Measurements have shown, for example, that a moving clock does run more slowly.

Communicate Research the life of Albert Einstein and make a time line showing important events in his life. Also include on your time line major historical events that occurred during Einstein's lifetime.

TIME

For more information, visit
fl.gpscience.com

Communicate Encourage students to include international events; examine how these events impacted Einstein's research. Also, there are many visual metaphors and cartoons available to explain Einstein's theories in simple terms. Go to fl.gpscience.com for more information.

Resources for Teachers and Students

Albert Einstein: Physicist and Genius by Joyce Goldenstern, Enslow Publishers, Inc., 1994

Einstein's Universe by Nigel Calder, Random House Value Publishing, Inc., 1990

Reviewing Main Ideas

Section 1

What are electromagnetic waves?

1. Electromagnetic waves consist of vibrating electric and magnetic fields, and are produced by vibrating electric charges.

2. Electromagnetic waves carry radiant energy and can travel through a vacuum or through matter.
3. Electromagnetic waves sometimes behave like particles called photons.

Section 2

The Electromagnetic Spectrum

1. Electromagnetic waves with the longest wavelengths are called radio waves. Radio waves have wavelengths greater than about 1 mm. Microwaves are radio waves with wavelengths between about 30 cm and 1 mm.
2. Infrared waves have wavelengths between about 1 mm and 750 billionths of a meter. Warmer objects emit more infrared waves than cooler objects do.

3. Visible light rays have wavelengths between about 750 and 400 billionths of a meter. Substances in your eyes react with visible light to enable you to see.
4. Ultraviolet waves have frequencies between about 400 and 10 billionths of a meter. Excessive exposure to ultraviolet waves can damage human skin.
5. X rays and gamma rays are high-energy electromagnetic waves with wavelengths less than 10 billionths of a meter. X rays are used in medical imaging.

Section 3

Radio Communication

1. Modulated radio waves are used often for communication. AM and FM are two forms of carrier-wave modulation.
2. Television signals are transmitted as a combination of AM and FM waves.
3. Cellular telephones, cordless telephones, and pagers use radio waves to transmit signals. Communications satellites are used to relay telephone and television signals over long distances.
4. The Global Positioning System (GPS) enables the exact position of a person or object on Earth to be determined.

FOLDABLES Use the Foldable that you made at the beginning of this chapter to help you review electromagnetic radiation.

Reviewing Main Ideas

Summary statements can be used by students to review the major concepts of the chapter.

Assessment

Assessment Transparency Electromagnetic Waves Chapter 15

Directions: Carefully review the table and answer the following questions.

Type of wave	Wavelength range (m)
Gamma rays	10^{-12} – 10^{-11}
X rays	10^{-11} – 10^{-8}
Ultraviolet	10^{-8} – 10^{-7}
Infrared	10^{-6} – 10^{-3}
Microwave	10^{-3} – 10^{-1}
Radio wave	10^{-1} – 10^4

1. Which of the following wavelengths could be broadcast by a rock-and-roll radio station?
 A. 10^{-12} meters C. 10^3 meters
 B. 10^{-8} meters D. 10^{-7} meters
2. If a device emits an electromagnetic wave with a wavelength of 10^{-10} meters, then it is probably _____.
 F an X ray machine
 G an AM/FM car radio
 H a microwave
 I a light bulb
3. Food can be heated rapidly in your own home using an electromagnetic wave with a wavelength of _____.
 A. 10^{-12}
 B. 10^{-8}
 C. 10^{-7}
 D. 100

L2

FOLDABLES Have students use their Foldables to review the content of the chapter. On the back of the paper, have students explain how they would likely make use of each type of electromagnetic wave in the course of their day.

Using Vocabulary

- Radio waves
- infrared waves
- radiant energy
- ultraviolet waves
- carrier waves
- cathode ray tube
- electromagnetic waves

Checking Concepts

- A
- D
- B
- A
- C
- B
- A

Interpreting Graphics

- See student page.
- See student page.

Thinking Critically

- They have enough energy to pass through the body's soft tissue but still be blocked by hard tissue. This causes a shadow image of the hard tissue to be formed on photographic film.
- No, because the electric field must be changing to produce the magnetic field and the magnetic field must be changing to produce the electric field.
- Visible light has a very high frequency, on the order of 10^{15} Hz. The magnetic field in visible light changes direction much too rapidly for the compass needle to respond.
- Answers will vary.
- Possible answer: Ultraviolet waves would be absorbed by Earth's ozone layer.

Using Vocabulary

- | | |
|---------------------------------------|------------------------|
| carrier wave p.469 | microwave p.463 |
| cathode-ray tube p.472 | photon p.460 |
| ★ electromagnetic wave p.456 | radiant energy p.459 |
| gamma ray p.467 | radio wave p.463 |
| Global Positioning System (GPS) p.475 | transceiver p.473 |
| infrared wave p.464 | ultraviolet wave p.465 |
| | visible light p.462 |
| | X ray p.467 |

FCAT Vocabulary

Complete each statement using the correct word or phrase from the vocabulary list above.

- _____ are the type of electromagnetic waves often used for communication.
- A remote control uses _____ to communicate with a television set.
- Electromagnetic waves transmit _____.
- If you stay outdoors too long, your skin might be burned by exposure to _____ from the Sun.
- A radio station broadcasts radio waves called _____, which have the specific frequency assigned to the station.
- The image on a television screen is produced by a _____.
- Transverse waves that are produced by vibrating electric charges and consist of vibrating electric and magnetic fields are _____.

Checking Concepts

Choose the word or phrase that best answers each question.

- Which type of electromagnetic wave is the most energetic?
 - gamma rays
 - ultraviolet waves
 - infrared waves
 - microwaves

Use the figure below to answer question 9.

- What signal has the longest wavelength?
 - cell phone
 - TV
 - FM
 - AM
- Which type of electromagnetic wave enables skin cells to produce vitamin D?
 - visible light
 - ultraviolet waves
 - infrared waves
 - X rays
- Which of the following describes X rays?
 - short wavelength, high frequency
 - short wavelength, low frequency
 - long wavelength, high frequency
 - long wavelength, low frequency
- Which of the following is changing in an AM radio wave?
 - speed
 - frequency
 - amplitude
 - wavelength
- Which type of electromagnetic wave has wavelengths greater than about 1 mm?
 - X rays
 - radio waves
 - gamma rays
 - ultraviolet waves
- Which of these colors of visible light has the shortest wavelength?
 - blue
 - green
 - red
 - white

Use the ExamView® Pro Testmaker CD-ROM to:

- edit existing questions and add your own questions
- build tests aligned with state standards using built-in State Curriculum Tags
- change English tests to Spanish with one mouse click and vice versa

Interpreting Graphics

15. Copy and complete the following table about the electromagnetic spectrum.

Uses of Electromagnetic Waves

Type of Electromagnetic Waves	Examples of How Electromagnetic Waves Are Used
radio waves	radio, TV transmission
Infrared waves	remote control transmitters
Visible light	vision
ultraviolet light	fluorescent materials
X rays	medical imaging
gamma rays	destroying harmful cells

16. Copy and complete the following events chain about the destruction of ozone molecules in the ozone layer by CFC molecules.

Thinking Critically

17. **Explain** why X rays are used in medical imaging.
18. **Predict** whether an electromagnetic wave would travel through space if its electric and magnetic fields were not changing with time. Explain your reasoning.

19. **Infer** Electromagnetic waves consist of vibrating electric and magnetic fields. A magnetic field can move a compass needle. Why doesn't a compass needle move when visible light strikes the compass?
20. **Classify** Look around your home, school, and community. Make a list of the different devices that use electromagnetic waves. Beside each device, write the type of electromagnetic wave the device uses.
21. **Form a hypothesis** to explain why communications satellites don't use ultraviolet waves to receive information and transmit signals to Earth's surface.
22. **Compare** the energy of photons corresponding to infrared waves with the energy of photons corresponding to ultraviolet waves.
23. **Determine** whether or not all electromagnetic waves always travel at the speed of light. Explain.

Applying Math

24. **Use Fractions** When visible light waves travel in ethyl alcohol, their speed is three-fourths of the speed of light in air. What is the speed of light in ethyl alcohol?
25. **Use Scientific Notation** The speed of light in a vacuum has been determined to be 299,792,458 m/s. Express this number to four significant digits using scientific notation.
26. **Calculate Wavelength** A radio wave has a frequency of 540,000 Hz and travels at a speed of 300,000 km/s. Use the wave speed equation to calculate the wavelength of the radio wave. Express your answer in meters.

22. Photons corresponding to electromagnetic waves with higher frequencies have greater energy; photons corresponding to ultraviolet waves will have greater energy than infrared photons.
23. No. They travel at their maximum speed in a vacuum. When moving through matter their speed is slower.

Applying Math

Math Standards

National: 1, 2, 9

Florida: MA.A.1.4.4, MA.D.1.4.1

24. 225,000 km/s

25. 2.998×10^8 m/s

26. $v = f\lambda$, so $\lambda = v/f =$
 $\frac{(300,000 \text{ km/s})}{(540,000 \text{ Hz})} =$
 0.55 km = 550 m

Standardized Test Practice Answer Sheet

Multiple Choice

1. ☐ A ☐ B ☐ C ☐ D

2. ☐ A ☐ B ☐ C ☐ D

3. ☐ A ☐ B ☐ C ☐ D

Gridded Response

1	A	2	D
3	B	4	C
5	C	6	B
7	D		

Go On

Multiple Choice

1. A
2. D
3. B
4. C
5. C
6. B
7. D

Record your answers on the answer sheet provided by your teacher or on a sheet of paper.
The assessed Florida Benchmark appears above the question.

Multiple Choice

SC.B.1.4.4

1. Which of the following produces electromagnetic waves?
 - A. vibrating charge
 - B. constant electric field
 - C. static charge
 - D. constant magnetic field

Use the photograph below to answer questions 2 and 3.

2. A television image is produced by three electron beams. What device inside a television set produces the electron beams?
 - A. transceiver
 - B. transmitter
 - C. antenna
 - D. cathode-ray tube

Test-Taking Tip

Marking on Tests Be sure to ask if it is okay to write on the test booklet when taking the test, but make sure you mark all answers on your answer sheet.

3. What colors are the three types of glowing spots that form the different colors on the television screen?
 - A. red, yellow, blue
 - B. red, green, blue
 - C. cyan, magenta, yellow
 - D. cyan, magenta, blue
4. Which of the following explains how interference is avoided between the signals communications satellites receive and the signals they broadcast?
 - A. The signals travel at different speeds.
 - B. The signals have different amplitudes.
 - C. The signals have different frequencies.
 - D. The signals are only magnetic.

Use the table below to answer questions 5 and 6.

Regions of the Electromagnetic Spectrum		
Infrared waves	Radio waves	Gamma rays
X rays	Visible light	Ultraviolet waves

5. If you arranged the list of electromagnetic waves shown above in order from shortest to longest wavelength, which would be first on the list?
 - A. radio waves
 - B. X rays
 - C. gamma rays
 - D. visible light

6. Which region of the electromagnetic spectrum listed in the table above includes microwaves?

A. gamma rays
B. radio waves
C. ultraviolet waves
D. infrared waves

7. The warmth you feel when you stand in front of a fire is thermal energy transmitted to you by what type of electromagnetic waves?

A. X rays
B. microwaves
C. ultraviolet waves
D. infrared waves

Gridded Response

8. Electromagnetic radiation travels through space at 3.00×10^5 km/s. The moon is, on average, 382,000 km from Earth. How many seconds would it take radio waves broadcast from Earth to reach the moon?

Short Response

Use the illustrations below to answer question 9.

9. The illustrations above show two radio waves broadcast by a radio station. The upper, unmodulated wave is the carrier wave. The lower figure shows the same wave that has been modulated to carry sound information. What type of modulation does it show?

10. Even on a cloudy day, you can get sunburned outside. However, inside a glass greenhouse, you won't get sunburned. Based on this fact, which type of electromagnetic waves will pass through clouds but not glass?

Extended Response

11. Explain how an electromagnetic wave that strikes a material transfers radiant energy to the atoms in the material.

Use the illustration below to answer question 12.

12. The illustration above shows a microwave interacting with water molecules in food.

Part A How does the electric field in microwaves affect water molecules?

Part B Describe how thermal energy is produced by microwaves interacting with water molecules inside food.

Gridded Response

8. 1.27

Short Response

9. AM, amplitude modulation
10. ultraviolet waves

Extended Response

11. by causing charged particles within articles to vibrate

12. Sample Answers

Part A: causes water molecules to rotate back and forth

Part B: The friction that occurs as rotating water molecules interact with each other is converted into thermal energy.

Section Focus

Section Focus Transparency For Peat's Sake 16

Peat, part of the peat bog, is an important part of the world for thousands of years. Over time, peat bogs have been used for many purposes. Peat bogs are probably more familiar to you than you think.

How might peat be used for fuel?
Peat comes from an swampy area called a bog. What is a bog?
How do people use energy from a peat bog?

L2

Section Focus Transparency Atomic Core 16

The first atomic power plant was built in 1954. It was the first of a series of nuclear power plants. The energy released by nuclear reactions is used to create electricity. The photo below shows the core of a nuclear reactor waiting to be moved to its permanent location.

How might nuclear energy be transformed into electrical energy?
How might nuclear power plants create a problem for the environment?
How can they be solved?

L2

Section Focus Transparency Sun Power! 16

Solar energy is the energy that comes from the sun. It is the most abundant source of energy on Earth. It can be used for many purposes. The photo below shows a solar panel array.

What might be the advantages of using solar energy?
What are the disadvantages?
Some solar energy is used to create electricity. How is it used?
What are some other uses of solar energy?

L2

This is a representation of key blackline masters available in the Teacher Classroom Resources. See Resource Manager boxes within the chapter for additional information.

Assessment

Assessment Transparency Energy Sources 16

Group A		Group B	
Energy	Percent of energy consumed in U.S.	Energy	Percent of energy consumed in U.S.
Coal	51%	Hydroelectric	7%
Natural gas	33%	Wind	0.5%
Petroleum	35%	Solar	0.001%
Nuclear	8%	Geothermal	0.001%
		Biomass	0.1%

The energy sources in Group A are different from the energy sources in Group B because the energy sources in Group A are nonrenewable resources. The energy sources in Group B are renewable resources. The energy sources in Group A are used to generate electricity. The energy sources in Group B are used to generate electricity. According to the table, which energy source supplies greater than 25% of the energy consumed in the U.S.?
1. Coal
2. Natural gas
3. Petroleum
4. Nuclear
5. Hydroelectric
6. Wind
7. Solar
8. Geothermal
9. Biomass

According to the table, what percent of the energy used in the U.S. comes from fossil fuels?
1. 51%
2. 33%
3. 35%
4. 8%

Science Content Background

section

1

Fossil Fuels**Making Fossil Fuels**

Fossil fuels were once living organisms that obtained energy directly or indirectly from the Sun and can therefore be considered a type of solar energy. Unlike the direct use of solar energy, burning fossil fuels produces carbon dioxide gas and other pollutants.

Kerosene was once the most important product from petroleum because of its use in kerosene lanterns. Kerosene is now used mainly as a fuel for jet engines.

Generating Electricity

Whether using fossil fuels, geothermal energy, or nuclear power, the generation of electricity involves heating water to produce steam to turn turbines. Hydropower, wind, and tidal energy turn turbines, but water is not heated to produce steam.

Teacher to Teacher

Erin Peters,
Lead Science Teacher
Williamsburg Middle School
Arlington, VA

"I ask the students to think of an activity such as doing your homework. Trace the energy sources back to the Sun. For example, pushing your pencil is mechanical energy, which comes from the chemical energy of eating lunch, which comes from food, which gets its energy from the Sun."

Erin Peters

section

2

Nuclear Energy**Using Nuclear Energy**

When nuclear fission and nuclear fusion occur, a small amount of mass is converted into energy. The connection between mass and energy is given by Einstein's famous equation $E=mc^2$. This equation showed that a small amount of mass is converted into an enormous amount of energy.

Gamma ray exposure is sometimes compared to the equivalent exposure in X rays. For example, a nuclear weapons worker may have had a yearly dose that is equivalent to one chest X ray. Compared to X rays or other types of nuclear radiation, gamma rays are the most energetic. As a result, they penetrate the farthest into living tissue and can cause the most biological damage.

France is the world leader in electrical power generation from nuclear fission. Approximately three-quarters of France's electrical energy is generated by this process.

The only approved permanent storage site in the United States for radioactive wastes is Yucca Mountain in Nevada. Some scientists believe this is a good site because it is far from major populations, it has low levels of rainfall, and the water table is very deep.

Section 3 Renewable Energy Sources Energy from the Sun

The materials required to generate electricity from solar energy are expensive. The materials to use the Sun's energy for heating are, however, relatively inexpensive. Piping and a box with a glass roof are the fundamental parts of many solar water heaters. Currently about one million homes in the United States use solar water heating. Some states, such as North Carolina and Arizona, give tax incentives for the installation of solar water heaters. Passive solar heating of spaces in houses is another low-cost way to use the Sun's energy. New houses are increasingly being designed with windows facing the south to absorb the Sun's energy in wintertime. Overhangs on the houses prevent the Sun's entry in the summertime.

Energy from Inside Earth

You don't need to live near a volcano to use geothermal energy. Heat pumps, in use in 400,000 United States homes, take advantage of fairly constant below-ground temperatures. The temperature range in the first ten feet of soil is 10° to 15.5°C (50° to 60°F). This usually means the soil is warmer than the winter air and cooler than the summer air. In a heat pump, air either gains or loses heat to the ground before entering a heating or cooling unit.

Alternative Fuels

When animal manure is decomposed by anaerobic fermentation, methane gas is produced. This can be collected and used as a source of fuel for, among other things, generating electricity. Farms with 700 head of cattle can produce enough methane to power approximately 50 homes. Methane is a greenhouse gas, and this process helps prevent additional methane from entering the atmosphere.

Energy Sources

chapter preview

sections

- 1 Fossil Fuels
- 2 Nuclear Energy
- 3 Renewable Energy Sources

Lab Solar Heating

Lab How much does energy really cost?

Virtual Lab How much electricity is used in a house?

That's a lot of kilowatts!

Look closely at this photo. Can you identify at least three items that require energy to operate? The welding torches require energy to join the pieces of the car together. The robots require energy to assemble the pieces. When the car is finished, energy will be required to operate the car.

Science Journal Describe how your day would be different if the electric power were off all day.

484

Theme Connection

Energy People use energy from many different sources. Fossil fuels are the primary source of energy, but nuclear reactions, solar power, hydroelectric power, and geothermal power also are used.

About the Photo

Robot Workers The 1970s energy crisis began a major push to automate manufacturing processes in the United States. Recent developments in robots used in automobile manufacturing can significantly reduce energy needs of a factory and thereby reduce environmental pollutants, such as carbon dioxide, by as much as 50 percent.

Start-Up Activities

Heating with Solar Energy

The Sun constantly bathes our planet with enormous amounts of energy. This energy can be captured and used to make electricity, heat homes, and provide hot water. How can the Sun's energy be used to heat water?

1. Use scissors to poke a small hole in the center of two coffee can lids.
2. Fill a coffee can that has been painted black with water at room temperature. Snap on the lid and push a thermometer through the hole in the lid. Record the temperature.
3. Repeat step 2 using the coffee can that has been painted white.
4. Place both cans in direct sunlight. After 15 min, record the temperature of the water in both cans again.
5. **Think Critically** Write a paragraph explaining why the temperature change differed between the two cans.

FOLDABLES™ Study Organizer

Energy Sources There are many sources of energy. Make the following Foldable to help you organize information about various types of energy sources.

- STEP 1** Fold a sheet of paper in half lengthwise. Make the back edge about 5 cm longer than the front edge.

- STEP 2** Turn the paper so the fold is on the bottom. Then fold it into thirds.

- STEP 3** Unfold and cut only the top layer along both folds to make three tabs.

- STEP 4** Label the Foldable as shown.

Summarize As you read this chapter, summarize important information about each type of energy source under the appropriate tab.

Purpose Use the Launch Lab to show students how one form of energy can be transformed into another form that we can use.

L2 ELL AS Kinesthetic

Preparation To save time, you may want to paint coffee cans and cut holes in the lids ahead of time.

Materials scissors, coffee cans with lids, white paint, black paint, water, thermometer

Teaching Strategy Identify a place that gets direct sunlight where students can leave the cans for 15 minutes.

Think Critically

The temperature change is greater in the black can because the color black absorbs more energy than the color white.

Assessment

Process Ask students to make data tables and to record in the tables the temperature readings for each can every two minutes. Use **Performance Assessment in the Science Classroom**, p. 109.

FOLDABLES™ Study Organizer

Section Focus Transparencies also are available on the Interactive Chalkboard CD-ROM.

L2 ELL

Section Focus Transparency For Peat's Sake

Dried peat has been used as fuel in many parts of the world for hundreds of years. Given enough time and pressure, peat will form a fuel you are probably more familiar with—coal!

1. How might peat be used for fuel?
2. Peat comes from swampy areas called bogs. What do you think peat is composed of?
3. How do people use energy in their everyday lives?

L2

Tie to Prior Knowledge

Energy Source Ask students to name the last time they rode in a bus or car. Tell them that the energy that made the vehicle move came from fossil fuels. In this section, they will learn about various types of fossil fuels that are useful sources of energy.

Activate Vocabulary Knowledge

Ask students to identify the ways in which the new vocabulary words are connected. Allow students to use the text as a resource. Have them identify other familiar terms that could be connected to the vocabulary words.

Reading Guide

What You'll Learn

- **Discuss** properties and uses of fossil fuels.
- **Explain** how fossil fuels are formed.
- **Describe** how the chemical energy in fossil fuels is converted into electrical energy.

Why It's Important

Fossil fuels are used to generate most of the energy you use every day.

Review Vocabulary

chemical potential energy: the energy stored in the chemical bonds between atoms in molecules

New Vocabulary

- fossil fuel
- petroleum
- nonrenewable resource

Using Energy

How many different ways have you used energy today? Today you might have ridden in a car or bus, or used a hair dryer or a toaster. If you did, you used energy. Furnaces and stoves use thermal energy to heat buildings and cook food. Air conditioners use electrical energy to move thermal energy outdoors. Cars and other vehicles use mechanical energy to carry people and materials from one part of the country to another.

Transforming Energy According to the law of conservation of energy, energy cannot be created or destroyed. Energy can only be transformed, or converted, from one form to another. To use energy means to transform one form of energy to another form of energy that can perform a useful function. For example, energy is used when the chemical energy in fuels is transformed into thermal energy that heats your home.

Sometimes energy is transformed into a form that isn't useful. For example, power lines, like those shown in **Figure 1**, carry electrical energy. When electric current flows in power lines, about 10 percent of the electrical energy is transformed into thermal energy. This thermal energy flows into the air surrounding the power lines, and can no longer be used.

Figure 1 Power lines like these carry the electrical energy you use every day.

Fun Fact

Fossil fuels currently supply nearly 90 percent of all the energy consumed by the industrially developed nations of the world

Caption Answer

Figure 3 about 4:1

Discussion

Fossil Fuels Are fossil fuels still being made today? The physical and chemical processes that made fossil fuels are still acting on decaying organic matter on Earth's crust. However, the rate at which new fuel is being made is tiny compared with the rate at which it is being used. [L3]

 **Logical-Mathematical**

Reading Strategy

K-W-L Chart Have students set up a three-column chart. In the first column, students will indicate what they know about Petroleum, Natural Gas, Coal, and Electricity Generation. In the second column, they will state what they want to know about each. Finally, after reading, students will state what they've learned about the topics.

Energy Use in the United States

More energy is used in the United States than in any other country in the world. **Figure 2** shows energy usage in the United States. About 20 percent of the energy is used in homes for heating and cooling, to run appliances, and to provide lighting and hot water. About 27 percent is used for transportation powering vehicles such as cars, trucks, and aircraft.

Another 16 percent is used by businesses to heat, cool, and light stores, shops, and office buildings. Finally, about 37 percent of this energy is used by industry and agriculture to manufacture products and produce food. **Figure 2** also shows the main sources of the energy used in the United States. Almost 85 percent of the energy used in the United States comes from burning petroleum, natural gas, and coal. Nuclear power plants provide about eight percent of the energy used in the United States.

Making Fossil Fuels

In one hour of freeway driving a car might use several gallons of gasoline. It may be hard to believe that it took millions of years to make the fuels that are used to produce electricity, provide heat, and transport people and materials. **Figure 4** on the next page shows how coal, petroleum, and natural gas are formed by the decay of ancient plants and animals. Fuels such as petroleum, or oil, natural gas, and coal are called **fossil fuels** because they are formed from the decaying remains of ancient plants and animals.

Concentrated Energy Sources When fossil fuels are burned, carbon and hydrogen atoms combine with oxygen molecules in the air to form carbon dioxide and water molecules. This process converts the chemical potential energy that is stored in the chemical bonds between atoms to heat and light. Compared to other fuels such as wood, the chemical energy that is stored in fossil fuels is more concentrated. For example, burning 1 kg of coal releases two to three times as much energy as burning 1 kg of wood. **Figure 3** compares the amount of energy that is produced by burning different fossil fuels.

Energy Usage

Sources of Energy

Figure 2 These circle graphs show where energy is used in the United States and sources of this energy.

Figure 3 The bar graph shows the amount of energy released by burning one gram of four different fuels.

Determine the ratio of the energy content of natural gas to the energy content of wood.

Differentiated Instruction

Challenge Ask students to find out how much energy is used per person in other developed nations, compared with the amount used in the United States. Have students make a graph showing their results. **In most other developed nations, about half as much energy is used per person as is used in the United States.** [L3]  **Logical-Mathematical**

Curriculum Connection

Language Arts Power outages sometimes occur because of severe snowstorms, flooding, or other natural disasters. Have each student write a story about how he or she would survive an imaginary week-long loss of electricity, natural gas, and gasoline. Students should describe their daily routines and include ideas for alternate sources of energy. [L2]  **Linguistic**  **P**

Visualizing the Formation of Fossil Fuels

Have students examine the pictures and read the captions. Then ask the following question.

Why do oil and gas sometimes bubble to the surface, while coal never does? Oil (a liquid) and natural gas (a gas) are less dense than the surrounding rock. Coal is a solid and its density is not low enough for it to rise to the surface.

Activity

Fossil Fuel Concentrations Divide the class into three groups. Assign each group a different fossil fuel: coal, oil, and natural gas. Have students in each group research the locations of deposits of the fuel and plot the distribution on an outline map of the world. Display the three maps and discuss which parts of the world have the largest concentrations of each fossil fuel. [L2]

 Visual-Spatial

Teacher FYI

OPEC The Organization of Petroleum Exporting Countries (OPEC) is a group of eleven countries that own most of the world's crude oil reserves. They work together to coordinate petroleum policy. Member nations are Algeria, Indonesia, Iran, Iraq, Kuwait, Libya, Nigeria, Qatar, Saudi Arabia, the United Arab Emirates, and Venezuela.

Figure 4

Oil and natural gas form when organic matter on the ocean floor, gradually buried under additional layers of sediment, is chemically changed by heat and crushing pressure. The oil and gas may bubble to the surface or become trapped beneath a dense rock layer. Coal forms when peat—partially decomposed vegetation—is compressed by overlying sediments and transformed first into lignite (soft brown coal) and then into harder, bituminous coal. These two processes are shown below.

HOW OIL AND NATURAL GAS ARE FORMED

HOW COAL IS FORMED

Differentiated Instruction

Challenge Have students research the discoveries of bog mummies that have been made by peat cutters in northern Europe where peat is still sometimes used as a fuel. Have students write reports on the conditions that caused the peat bogs to form and that also mummified the bodies. [L3]  Linguistic

Petroleum

Millions of gallons of petroleum, or crude oil, are pumped every day from wells deep in Earth's crust. **Petroleum** is a highly flammable liquid formed by decayed ancient organisms, such as microscopic plankton and algae. Petroleum is a mixture of thousands of chemical compounds. Most of these compounds are hydrocarbons, which means their molecules contain only carbon atoms and hydrogen atoms.

Separating Hydrocarbons The different hydrocarbon molecules found in petroleum have different numbers and arrangements of carbon and hydrogen atoms. The composition and structure of hydrocarbons determines their properties.

The many different compounds that are found in petroleum are separated in a process called fractional distillation. This separation occurs in the tall towers of oil-refinery plants. First, crude oil is pumped into the bottom of the tower and heated. The chemical compounds in the crude oil boil and vaporize according to their individual boiling points. Materials with the lowest boiling points rise to the top of the tower as vapor and are collected. Hydrocarbons with high boiling points, such as asphalt and some types of waxes, remain liquid and are drained off through the bottom of the tower.

 **Reading Check** What is fractional distillation used for?

Other Uses for Petroleum Not all of the products obtained from petroleum are burned to produce energy. About 15 percent of the petroleum-based substances that are used in the United States go toward nonfuel uses. Look around at the materials in your home or classroom. Do you see any plastics? In addition to fuels, plastics and synthetic fabrics are made from the hydrocarbons found in crude petroleum. Also, lubricants such as grease and motor oil, as well as the asphalt used in surfacing roads, are obtained from petroleum. Some synthetic materials produced from petroleum are shown in **Figure 5**.

Figure 5 The objects shown here are made from chemical compounds found in petroleum.

Identify four objects in your classroom that are made from petroleum.

Mini LAB

Designing an Efficient Water Heater

Procedure

1. Measure and record the mass of a candle.
2. Measure 50 mL of water into a beaker. Record the temperature of the water.
3. Use the lighted candle to increase the temperature of the water by 10°C. Put out the candle and measure its mass.
4. Repeat steps 1 to 3 with an aluminum foil chimney surrounding the candle.

Analysis

1. Compare the mass change in the two trials. Which heater was more efficient?
2. Explain why adding the chimney changed the efficiency of the water heater.

Mini LAB

Purpose Students determine how heating efficiency can be improved.   

Kinesthetic

Materials candle, water, foil, 100-mL beaker, thermometer, ring stand and ring, balance, wire gauze, graduated cylinder

Teaching Strategies

- Demonstrate how to set up the equipment. Place wire gauze between the ring stand and the beaker for more even heating.
- Encourage students to experiment with the chimney size, shape, and location. Soot on the beaker improves the efficiency of heating.

Analysis

1. The mass changes less when the chimney is used. The chimney heater was more efficient because less of the candle was needed to raise the temperature of the water.
2. The chimney directed the thermal energy from the candle to the beaker.

Assessment

Oral How would the results differ if the temperature of the water were increased by 30°C in each case? There would be a greater change in the candle's mass, especially if the chimney were not used.

Reading Check

Answer to separate the many different compounds found in petroleum

Caption Answer

Figure 5 Student answers will vary but may include tennis shoes, plastic chairs, plastic trash bags, and synthetic fabrics such as fleece, polyester, nylon, and rayon.

Cultural Diversity

Oil-Rich Countries More than 65 percent of the world's oil reserves are in the Middle East. Have students research some of the changes that have occurred in these countries since oil was discovered in them. Possible answer: The economies of these countries are now based on income from the sale of oil. They have better health care, roads, schools, and other public facilities than they had before.   **Linguistic**

Curriculum Connection

History In 1973, the Arab oil embargo caused an energy crisis in the United States that forced people to carefully examine their dependence on oil. Have groups of students research this topic and create computer presentations about related major events since that time. Topics might include the economic recession caused by the oil crisis or causes of the Persian Gulf War.   **Interpersonal**

Discussion

Odorless Gas Natural gas has almost no odor. Why might natural gas distributors add an odorant to the gas? **so you can tell if there is a gas leak** **L2** **IS** **Logical-Mathematical**

Inquiry Lab

Conserving Resources

Purpose to survey fellow students' efforts to conserve energy, to compile results, and to offer energy conservation tips and techniques

Possible Materials copies of student-generated survey to pass out to fellow students

Estimated Time 2 class periods or 2 hours outside of class

Teaching Strategies

- Students should be divided into small groups. Have students write a student survey that will ask questions about energy conservation, such as "Do you turn the lights off when you leave the room?"
- Students should compile the results of the survey. Students can use their math skills to determine the percentages of the types of responses.
- Have students prepare a brochure to be distributed to students in their school presenting their compilation and tips and techniques for conserving energy.

For additional inquiry activities, see *Science Inquiry Lab*.

Figure 6 Coal mines usually are located deep underground.

Natural Gas

The chemical processes that produce petroleum as ancient organisms decay also produce gaseous compounds called natural gas. These compounds rise to the top of the petroleum deposit and are trapped there. Natural gas is composed mostly of methane, CH_4 , but it also contains other hydrocarbon gases such as propane, C_3H_8 , and butane, C_4H_{10} . Natural gas is burned to provide energy for cooking, heating, and manufacturing. About one fourth of the energy consumed in the United States comes from burning natural gas. There's a good chance that your home has a stove, furnace, hot-water heater, or clothes drier that uses natural gas.

Natural gas contains more energy per kilogram than petroleum or coal does. It also burns more cleanly than other fossil fuels, produces fewer pollutants, and leaves no residue such as ash.

Coal

Coal is a solid fossil fuel that is found in mines underground, such as the one shown in **Figure 6**. In the first half of the twentieth century, most houses in the United States were heated by burning coal. In fact, during this time, coal provided more than half of the energy that was used in the United States. Now, almost two-thirds of the energy used comes from petroleum and natural gas, and only about one-fourth comes from coal. About 90 percent of all the coal that is used in the United States is burned by power plants to generate electricity.

490 CHAPTER 16 Energy Sources

Differentiated Instruction

Challenge Fluidized-bed combustion of coal burns coal more efficiently and produces fewer pollutants than conventional coal boilers. Have students find out more about this technology. Have students draw a diagram detailing how this process works. **L3** **IS** **Logical-Mathematical**

Teacher FYI

U.S. Coal Reserves The four largest coal reserves in the United States are the Four Corners Region near northern New Mexico, the Powder River Basin in Montana and Wyoming, the Eastern Interior Region around Illinois, and the Appalachian Region from Pennsylvania to Alabama.

Origin of Coal Coal mines were once the sites of ancient swamps. Coal formed from the organic material that was deposited as the plants that lived in these swamps died. Worldwide, the amount of coal that is potentially available is estimated to be 20 to 40 times greater than the supply of petroleum.

Coal also is a complex mixture of hydrocarbons and other chemical compounds. Compared to petroleum and natural gas, coal contains more impurities, such as sulfur and nitrogen compounds. As a result, more pollutants, such as sulfur dioxide and nitrogen oxides, are produced when coal is burned.

Generating Electricity

Figure 7 shows that almost 70 percent of the electrical energy used in the United States is produced by burning fossil fuels. How is the chemical energy contained in fossil fuels converted to electrical energy in an electric power station?

The process is shown in **Figure 8**. In the first stage, fuel is burned in a boiler or combustion chamber, and it releases thermal energy. In the second stage, this thermal energy heats water and produces steam under high pressure. In the third stage, the steam strikes the blades of a turbine, causing it to spin. The shaft of the turbine is connected to an electric generator. In the fourth stage, electric current is produced when the spinning turbine shaft rotates magnets inside the generator. In the final stage, the electric current is transmitted to homes, schools, and businesses through power lines.

Sources of Electricity

Figure 7 This circle graph shows the percentage of electricity generated in the United States that comes from various energy sources.

Figure 8 Fossil fuels are burned to generate electricity in a power plant. **Determine** which stage in this process is the most inefficient.

Visual Learning

Figure 7 Review with students the information shown in **Figure 7**. What are the percentages of the three energy sources that are fossil fuels? What do they add up to? **Coal 51%, natural gas 14%, and petroleum 4%. These add up to 69%.** **L2** **Visual-Spatial**

Curriculum Connection

History Electricity has been a major source of power in the United States for less than 100 years. Have students research the early history of the use of electricity in the United States. **In 1882, Edison opened an electric power plant that lit light bulbs. The first electric power was direct current. Power plants now produce alternating current.** **L3** **Linguistic**

Quick Demo Coal Formation

Materials peat; four different types of coal such as lignite, sub-bituminous, bituminous, and anthracite

Estimated Time 10 minutes

Procedure Have students examine the peat and the different types of coal. Have students infer how the coal was formed. What are the differences in the conditions that formed the coal? **The four types of coal are distinguished by the pressure that produced them. Lignite is produced when rock and soil pressed down on buried peat, causing it to dry out and harden. Further pressure produces subbituminous coal, then bituminous coal, and finally anthracite.**

L2 **Visual-Spatial**

Discussion

Power Sources Electricity became the major source of power in the United States during the twentieth century. What were the sources of power before that? **Possible answers include running water and steam.**

L2 **Logical-Mathematical**

Caption Answer

Figure 8 stage 1

Virtual Labs

Household Electricity How much electricity is used in a house?

Discussion

Energy Loss What is the primary way in which energy is lost in power plants? **Energy is lost as heat.**

Activity

Pollution Diagrams Have students draw diagrams showing how burning fossil fuels causes pollution. Diagrams might illustrate smog formed when fossil fuels are burned, and the effects of ozone near Earth's surface. Students might also draw plants using devices that remove the pollutants before they can reach the air. **L3** **IS** **Visual-Spatial** **P**

Discussion

Alternatives What might happen when readily available fossil fuels are used up? **Possible answers:** Alternative energy sources will be developed; companies will exploit more expensive sources of fossil fuels; people's way of life will change because energy will become more expensive to use. **L2** **IS** **Logical-Mathematical**

Table 1 Efficiency of Fossil Fuel Conversion

Process	Efficiency (%)
Chemical to thermal energy	60
Conversion of water to steam	90
Steam-turning turbine	75
Turbine spins electric generator	95
Transmission through power lines	90
Overall efficiency	35

Efficiency of Power Plants

When fossil fuels are burned in power plants, not all of the chemical energy stored in the fuels is converted into electrical energy. In each energy transformation, some energy is converted into thermal energy that cannot be used. As a result, no stage of the process is 100 percent efficient.

The efficiency of each stage of the process in a fossil-fuel burning power plant is given in **Table 1**. The overall efficiency is found by multiplying the efficiencies together, and is only about 35 percent. This means that only about

35 percent of the chemical energy contained in fossil fuels is converted into electrical energy by power plants. The other 65 percent is converted into thermal energy that is transferred to the environment.

The Costs of Using Fossil Fuels

Although fossil fuels are a useful source of energy for generating electricity and providing the power for transportation, their use has some undesirable side effects. When petroleum products and coal are burned, smoke is given off that contains small particles called particulates. These particulates cause breathing problems for some people. Burning fossil fuels also releases carbon dioxide. **Figure 9** shows how the carbon dioxide concentration in the atmosphere has increased from 1960 to 2000. One consequence of increasing the atmospheric carbon dioxide concentration could be to cause Earth's surface temperature to increase.

Figure 9 The carbon dioxide concentration in Earth's atmosphere has been measured at Mauna Loa in Hawaii. From 1960 to 2000, the carbon dioxide concentration has increased by about 16 percent.

Using Coal The most abundant fossil fuel is coal, but coal contains even more impurities than oil or natural gas. Many electric power plants that burn coal remove some of these pollutants before they are released into the atmosphere. Removing sulfur dioxide, for example, helps to prevent the formation of compounds that might cause acid rain. Mining coal also can be dangerous. Miners risk being killed or injured, and some suffer from lung diseases caused by breathing coal dust over long periods of time.

Differentiated Instruction

Learning Disabled To help students understand the math involved in finding the total efficiency of a power plant, discuss a two-step process in which the efficiency of the first step is 50 percent and the efficiency of the second step is 50 percent. Fill a beaker with water. Pour off half ($100\% \times 50\% = 50\%$). Then pour off half again ($50\% \times 50\% = 25\%$).

Nonrenewable Resources

All fossil fuels are **nonrenewable resources**, which means they are resources that cannot be replaced by natural processes as quickly as they are used. Therefore, fossil fuel reserves are decreasing at the same time that population and industrial demands are increasing. **Figure 10** shows how the production of oil might decline over the next 50 years as oil reserves are used up. As the production of energy from fossil fuels continues, the remaining reserves of fossil fuels will decrease. Fossil fuels will become more difficult to obtain, causing them to become more costly in the future.

Conserving Fossil Fuels

Even as reserves of fossil fuels decrease and they become more costly, the demand for energy continues to increase as the world's population increases. One way to meet these energy demands would be to reduce the use of fossil fuels and obtain energy from other sources.

Figure 10 Some predictions show that worldwide oil production will peak by 2005 and then decline rapidly over the following 50 years.

section 1 review

Summary

Using Energy

- Energy cannot be created or destroyed, but can only be transformed from one form to another.

Fossil Fuels

- Petroleum, natural gas, and coal are fossil fuels formed by the decay of ancient plants and animals.
- Petroleum is a mixture of thousands of chemical compounds, most of which are hydrocarbons.
- About 90 percent of all coal used in the United States is burned by power plants to produce electricity.

Generating Electricity

- Power plants burn fossil fuels to produce steam that spins turbines attached to electric generators.

Self Check

- Describe** the advantages and disadvantages of using fossil fuels to generate electricity.
- Explain** how the different chemical compounds in crude oil are separated.
- Describe** how fossil fuels are formed.
- Name** three materials that are derived from the chemical compounds in petroleum.
- Think Critically** If fossil fuels are still forming, why are they considered to be a nonrenewable resource?

Applying Math

- Interpret a Graph** According to the graph in **Figure 9**, by how many parts per million did the concentration of atmospheric carbon dioxide increase from 1960 to 2000?
- Use a Table** In **Table 1**, if the efficiency of converting chemical to thermal energy was 90 percent, what would the overall efficiency be?

section 1 review

- Advantages: Fossil fuels are an inexpensive source of energy. They are plentiful for the near-term; Disadvantages: Fossil fuels may cause environmental damage when removed from Earth, when transported, and when burned.
- They are separated by fractional distillation, in which each compound vaporizes at its own boiling point, rises, and is collected.
- Fossil fuels are formed when organic matter is chemically changed by heat and pressure.
- Possible answers: plastics, grease, gasoline, asphalt
- We are using fossil fuels faster than they are being replaced.
- about 50 parts per million
- 52 percent

Post Reading

Extended Research

Scientists predict that the demand for fossils fuels will increase while supplies continue to decrease. It will soon become necessary to consider alternative energy sources. Have students research alternatives to fossils fuels. They may report findings as a written paper or in a poster format.

3 Assess

DAILY INTERVENTION

Check for Understanding

Interpersonal Divide the class into small groups. Assign each group a topic from the section. Each group should present the main ideas from that section to the rest of the class.

Reteach

Evaluating Fossil Fuels Organize the class into teams of three. Have each team consider the advantages and disadvantages of using petroleum, natural gas, and coal. Have the teams combine their lists and report their conclusions. **L2 COOP LEARN**

Interpersonal

Assessment

Process Have students make a bulletin board comparing and contrasting the ways people obtain petroleum and coal. Petroleum is a liquid, so it is pumped from wells drilled deep into Earth's crust. Coal also comes from underground, but it is a solid, so it must be mined. Use **Performance Assessment in the Science Classroom**, p. 131.

Nuclear Energy

1 Motivate

The first self-sustaining nuclear reaction was achieved in 1942 by a team of scientists led by Enrico Fermi. Today, nuclear power plants use the energy released by nuclear reactions to create electricity. The photo below shows the core of a nuclear reactor waiting to be lowered into position underwater.

- How might nuclear energy be transformed into electrical energy?
- How might nuclear power plants reduce pollution from fossil fuels? Do you think there are any disadvantages to nuclear power?

L2

Reading Preview

Tie to Prior Knowledge

Nuclear Energy Uses Ask students to name ways that nuclear energy is used. **Possible answers:** diagnose and treat illnesses, nuclear weapons, generate power.

Predict and Anticipate Have students scan the section to find the new vocabulary words. Suggest that they read figures and captions to obtain clues to meaning. Ask students to anticipate how the words may be used in future chapters.

Reading Guide

What You'll Learn

- **Explain** how a nuclear reactor converts nuclear energy to thermal energy.
- **Describe** advantages and disadvantages of using nuclear energy to produce electricity.
- **Discuss** nuclear fusion as a possible energy source.

Why It's Important

Using nuclear energy to produce electricity can help reduce the use of fossil fuels. However, like all energy sources, the use of nuclear energy has advantages and disadvantages.

Review Vocabulary

nuclear fission: the process of splitting an atomic nucleus into two or more nuclei with smaller masses

New Vocabulary

- nuclear reactor
- nuclear waste

Using Nuclear Energy

Over the past several decades, electric power plants have been developed that generate electricity without burning fossil fuels. Some of these power plants, such as the one shown in **Figure 11**, convert nuclear energy to electrical energy. Energy is released when the nucleus of an atom breaks apart. In this process, called nuclear fission, an extremely small amount of mass is converted into an enormous amount of energy. Today almost 20 percent of all the electricity produced in the United States comes from nuclear power plants. Overall, nuclear power plants produce about eight percent of all the energy consumed in the United States. In 2003, there were 104 nuclear reactors producing electricity at 65 nuclear power plants in the United States.

Figure 11 A nuclear power plant generates electricity using the energy released in nuclear fission. Each of the domes contain a nuclear reactor. A cooling tower is on the left.

Nuclear Reactors

A **nuclear reactor** uses the energy from controlled nuclear reactions to generate electricity. Although nuclear reactors vary in design, all have some parts in common, as shown in **Figure 12**. They contain a fuel that can be made to undergo nuclear fission; they contain control rods that are used to control the nuclear reactions; and they have a cooling system that keeps the reactor from being damaged by the heat produced. The actual fission of the radioactive fuel occurs in a relatively small part of the reactor known as the core.

Reading Strategy

Visualize the Text Read the sections titled Nuclear Fuel, The Reactor Core, and Nuclear Fission aloud to students. As you read, ask students to close their eyes and imagine what is being described in the text. After listening to the reading, have students draw their visualizations.

Visual Learning

Figure 12 The distance the control rods extend into the reactor core controls the reaction. If the control rods are inserted completely, they absorb too many neutrons and the reaction halts. If they are removed completely, the reaction is uncontained. How do you think control rods are programmed to respond in an emergency? **They insert completely to stop the reaction.**

L2 **IS** Logical-Mathematical

Discussion

Rod-Shaped Why do you think the fuel and control used in the reactor are rod-shaped? **to allow the water to flow freely around them and provide cooling** **L2** **IS** Visual-Spatial

Quick Demo

Nuclear Fuel Pellets

Materials mini-marshmallows, test tubes (larger diameter than marshmallows), rubber band

Estimated Time five minutes

Procedure Use mini-marshmallows to represent the uranium dioxide fuel. Use test tubes to represent the reactor rods. Put the mini-marshmallows into the test tubes. Bundle several test tubes together with the rubber band to represent the bundled fuel rods.

Nuclear Fuel Only certain elements have nuclei that can undergo fission. Naturally occurring uranium contains an isotope, U-235, whose nucleus can split apart. As a result, the fuel that is used in a nuclear reactor is usually uranium dioxide. Naturally occurring uranium contains only about 0.7 percent of the U-235 isotope. In a reactor, the uranium usually is enriched so that it contains three percent to five percent U-235.

The Reactor Core The reactor core contains uranium dioxide fuel in the form of tiny pellets like the ones in **Figure 13**. The pellets are about the size of a pencil eraser and are placed end to end in a tube. The tubes are then bundled and covered with a metal alloy, as shown in **Figure 13**. The core of a typical reactor contains about a hundred thousand kilograms of uranium in hundreds of fuel rods. For every kilogram of uranium that undergoes fission in the core, 1 g of matter is converted into energy. The energy released by this gram of matter is equivalent to the energy released by burning more than 3 million kg of coal.

Figure 13 Nuclear fuel pellets are stacked together to form fuel rods. The fuel rods are bundled together, and the bundle is covered with a metal alloy.

Differentiated Instruction

Visually Impaired Use refillable erasers for mechanical pencils to symbolize the fuel pellets, allow students to feel what the fuel pellets are shaped like. A large soda straw can be used to symbolize the fuel rods. Students can put the erasers in the straw to symbolize packing the fuel rod.

Curriculum Connection

Social Studies The use of nuclear reactions in commercial power plants to produce electricity has been the subject of intense controversy. Organize the class into two teams and have them debate the issue. **Arguments for nuclear power include its efficiency and nonreliance on fossil fuels. Arguments against nuclear power include safety hazards and disposal of nuclear waste.** **L3** **IS** Logical-Mathematical

Use an Analogy

Foxes and Rabbits If rabbits live and breed in an environment rich in rabbit food but in which there are no rabbit predators, the rabbit population will boom very quickly. This is analogous to the uncontrolled chain reaction that can occur in a nuclear reactor. The introduction of foxes into the rabbit environment controls the size of the rabbit population just as the introduction of control rods controls the number of neutrons available to participate in the nuclear reaction.

Caption Answer

Figure 14 The neutrons strike other U-235 nuclei, breaking them apart into fission products and neutrons, or they are absorbed by control rods.

Reading Check

Answer a nuclear reaction in which the products of one reaction start another reaction

Make a Model

Reactor Core Have students work in pairs to make models of the core of a nuclear reactor. Models should include some fuel rods, some control rods, and a coolant. One possible model could use test tubes filled with different substances to represent the fuel rods and the control rods, a test tube rack to represent the core, and water as the coolant. [L2]

Kinesthetic

Uranium-Lead Dating The ratio of amounts of thorium-230 to uranium-234 has been used to date calcium carbonate. Rocks are also dated from the fossils they contain.

Figure 14 When a neutron strikes the nucleus of a U-235 atom, the nucleus splits apart into two smaller nuclei. In the process two or three neutrons also are emitted. The smaller nuclei are called fission products.

Explain what happens to the neutrons that are released in this reaction.

Nuclear Fission How does the nuclear reaction proceed in the reactor core? Neutrons that are produced by the decay of U-235 nuclei are absorbed by other U-235 nuclei. When a U-235 nucleus absorbs a neutron, it splits into two smaller nuclei and two or three additional neutrons, as shown in **Figure 14**. These neutrons strike other U-235 nuclei, causing them to release two or three more neutrons each when they split apart.

Because every uranium atom that splits apart releases neutrons that cause other uranium atoms to split apart, this process is called a nuclear chain reaction. In the chain reaction involving the fission of uranium nuclei, the number of nuclei that are split can more than double at each stage of the process. As a result, an enormous number of nuclei can be split after only a small number of stages. For example, if the number of nuclei involved doubles at each stage, after only 50 stages more than a quadrillion nuclei might be split.

Nuclear chain reactions take place in a matter of milliseconds. If the process isn't controlled, the chain reaction will release energy explosively rather than releasing energy at a constant rate.

Reading Check What is a nuclear chain reaction?

Controlling the Chain Reaction To control the chain reaction, some of the neutrons that are released when U-235 splits apart must be prevented from striking other U-235 nuclei. These neutrons are absorbed by rods containing boron or cadmium that are inserted into the reactor core. Moving these control rods deeper into the reactor causes them to absorb more neutrons and slow down the chain reaction. Eventually, only one of the neutrons released in the fission of each of the U-235 nuclei strikes another U-235 nucleus, and energy is released at a constant rate.

Uranium-Lead Dating

Uranium is used to determine the age of rocks. As uranium decays into lead at a constant rate, the age of a rock can be found by comparing the amount of uranium to the amount of lead produced. Uranium-lead dating is used by scientists to date rocks as old as 4.6 billion years. Research other methods used to determine the age of rocks.

Visual Learning

Figure 14 The tremendous energy from the fission process shown here is mostly transferred to the smaller nuclei and the neutrons, but part of the energy is released as gamma radiation. What are two ways a chain reaction can be avoided? **by introducing materials that absorb neutrons and by decreasing the amount of U-235 so there aren't enough atoms to continue the process** [L2] **Logical-Mathematical**

Active Reading

Think-Pair-Share This strategy encourages students to think first before discussing their ideas or thoughts about a topic. Students are asked to respond to a question by writing a response. After thinking for a few minutes, partners share responses to the question. Finally, ask students to share responses with the class.

Nuclear Power Plants

Nuclear fission reactors produce electricity in much the same way that conventional power plants do. **Figure 15** shows how a nuclear reactor produces electricity. The thermal energy released in nuclear fission is used to heat water and produce steam. This steam then is used to drive a turbine that rotates an electric generator. To transfer thermal energy from the reactor core to heat water and produce steam, the core is immersed in a fluid coolant. The coolant absorbs heat from the core and is pumped through a heat exchanger. There thermal energy is transferred from the coolant and boils water to produce steam. The overall efficiency of nuclear power plants is about 35 percent, similar to that of fossil fuel power plants.

The Risks of Nuclear Power

Producing energy from nuclear fission has advantages. Nuclear power plants do not produce the air pollutants that are released by fossil-fuel burning power plants. Also, nuclear power plants don't produce carbon dioxide.

The nuclear generation of electricity also has disadvantages. The mining of the uranium can cause environmental damage. Water that is used as a coolant in the reactor core must cool before it is released into streams and rivers. Otherwise, the excess heat could harm fish and other animals and plants in the water.

Ukraine The worst nuclear accident in history occurred at the Chernobyl nuclear power plant in the Ukraine in 1986. Many people in the area suffered from radiation sickness. Use a map or atlas to find the location of the Ukraine. Write a description of the location in your Science Journal.

Ukraine The Ukraine borders eastern Europe and is located east of Poland and north of Romania.

Research Have students research the Chernobyl accident. Have them find out what caused the accident and the damages that resulted from it.

Contaminated Water The water that is used as a coolant in reactor cores becomes contaminated with radioactive material. This water is not the same water that is cooled and released into streams and rivers. The water that is released into the environment does not come into direct contact either with the reactor core or with the water that cools the reactor core. It exchanges heat with the contaminated water through a heat exchanger.

Teacher FYI

Energy Supplies In an average American's lifetime, more than 1 million kg of coal would be needed to supply the person's energy needs. In contrast, if nuclear reactors were used instead of coal, about 1,100 uranium fuel pellets would be needed to supply the same amount of energy.

Figure 15 A nuclear power plant uses the heat produced by nuclear fission in its core to produce steam. The steam turns an electric generator.

SECTION 2 Nuclear Energy 497

Science Journal

Nuclear Power Plants Ask students to identify the nuclear power plant located closest to their community and write their findings in their Science Journals. Have them include the plant's name and location, when it began operation, how much electricity it generates, and its operating history. *Answers will depend on the location of their community.* [L3]

L Linguistic

Teacher FYI

Chernobyl After the Chernobyl accident in 1986, people all over the world became concerned about the safety of nuclear reactors. Although all reactors have some risks, reactors in the United States are far safer than the one in Chernobyl. Most importantly, the Chernobyl reactor did not have a containment shell that could prevent the escape of radioactive materials.

Activity

Nuclear Waste Disposal Ask students to generate ideas for nuclear waste disposal. Remind them to consider short-term and long-term effects as well as the various types of waste. Have students share their ideas in small groups and arrive at a class consensus about the best methods of disposal. **L2** **IS** **Interpersonal**

Figure 16 An explosion occurred at the Chernobyl reactor in the Ukraine after graphite control rods caught fire. The explosion shattered the reactor's roof.

caused a chemical explosion that blew a hole in the reactor, as shown in **Figure 16**. This resulted in the release of radioactive materials that were carried by winds and deposited over a large area. As a result of the accident, 28 people died of acute radiation sickness. In the United States, power plants are designed to prevent accidents such as the one that occurred at Chernobyl.

The Disposal of Nuclear Waste

After about three years, not enough fissionable U-235 is left in the fuel pellets in the reactor core to sustain the chain reaction. The spent fuel contains radioactive fission products in addition to the remaining uranium. These fuel pellets are a form of nuclear waste. **Nuclear waste** is any radioactive by-product that results when radioactive materials are used. Nuclear wastes are classified as low-level waste and high-level waste.

Low-Level Waste Low-level nuclear wastes usually contain a small amount of radioactive material. They usually do not contain radioactive materials with long half-lives. Products of some medical and industrial processes are low-level wastes, including items of clothing used in handling radioactive materials. Low-level wastes also include used air filters from nuclear power plants and discarded smoke detectors. Low-level wastes usually are sealed in containers and buried in trenches 30 m deep at special locations. When dilute enough, low-level waste sometimes is released into the air or water.

Science

Topic: Storing Nuclear Wastes

Visit fl.gpescience.com for Web links to information about storing nuclear wastes.

Activity Obtain a map or sketch an outline of the United States. Mark the locations of the nuclear waste sites that you found. What do these locations have in common? Why do you think these locations were chosen over other sites that were closer to the nuclear waste generating sites?

Differentiated Instruction

Challenge On March 28, 1979, an accident occurred at the Three-Mile Island Nuclear Plant near Harrisburg, Pennsylvania. Have students find out more about this incident and report their findings to the class. **The accident caused a small amount of**

hydrogen gas to escape the containment shell. Emergency cooling systems eventually contained the problem, but some radiation was released. This accident focused the nation's attention on the potential dangers of nuclear reactors. **L3** **IS** **Linguistic**

High-Level Waste High-level nuclear waste is generated in nuclear power plants and by nuclear weapons programs. After spent fuel is removed from a reactor, it is stored in a deep pool of water, as shown in **Figure 17**. Many of the radioactive materials in high-level nuclear waste have short half-lives. However, the spent fuel also contains materials that will remain radioactive for tens of thousands of years. For this reason, the waste must be disposed of in extremely durable and stable containers.

One method proposed for the disposal of high-level waste is to seal the waste in ceramic glass, which is placed in protective metal-alloy containers. The containers then are buried hundreds of meters below ground in stable rock formations or salt deposits. It is hoped that this will keep the material from contaminating the environment for thousands of years.

Figure 17 Spent nuclear fuel rods are placed underwater after they are removed from the reactor core. The water absorbs the nuclear radiation and prevents it from escaping into the environment.

Reading Check What is the difference between low-level and high-level nuclear wastes?

Applying Science

Can a contaminated radioactive site be reclaimed?

In the early 1900s, with the discovery of radium, extensive mining for the element began in the Denver, Colorado, area. Radium is a radioactive element that was used to make watch dials and instrument panels that glowed in the dark. After World War I, the radium industry collapsed. The area was left contaminated with 97,000 tons of radioactive soil and debris containing heavy metals and radium, which is now known to cause cancer. The soil was used as fill, foundation material, left in place, or mishandled.

Identifying the Problem

In the 1980s, one area became known as the Denver Radium Superfund Site and was cleaned up by the Environmental Protection Agency. The land then was reclaimed by a local commercial establishment.

Solving the Problem

1. The contaminated soil was placed in one area and a protective cap was placed over it. This area also was restricted from being used for residential homes. Explain why it is important for the protective cap to be maintained and why homes could not be built in this area.
2. The advantages of cleaning up this site are economical, environmental, and social. Give an example of each.

Discussion

Nuclear Waste Sites What are some problems that must be addressed when deciding on a site for nuclear waste? Safe transportation from other sites, possible terrorist plans for theft, political changes on policies and funding, proper storage capability to prevent the risk of radioactive materials from entering the environment L2

Logical-Mathematical

Reading Check

Answer Low-level nuclear wastes usually contain only a small amount of radioactive material with short half-lives. High-level nuclear wastes are usually highly radioactive and contain material with long half-lives.

Applying Science

Answers

1. The cap has to be maintained to prevent contaminated soil from reaching people. Homes can't be built in this area because all of the contaminated soil may not have been removed and some contamination may have reached the groundwater.
2. Advantages: Economic—jobs, revenue for the community, tax for the state, increase in property values; environmental—elimination of long-term risks for contaminated material, prevention of the migration of metals through the soil, protection of the public from contaminated land and water; social—improvement of the aesthetic quality of the land, commercial buildings can be built.

LAB DEMONSTRATION

Purpose to demonstrate how shielding decreases radiation levels

Materials alpha, beta, and gamma sources; Geiger counter; 3 lead sheets

Procedure Place the alpha source near the Geiger counter. Note the intensity measured by the counter. Place a lead sheet

between the source and the counter, and note the change in intensity. Repeat for the beta source using one lead sheet and for the gamma source using first one, then two, then three lead sheets.

Expected Outcome One lead sheet blocks the alpha and beta radiation. The intensity

of the gamma radiation decreases with additional shielding.

Assessment

How were measurements affected by the amount of shielding? Increased shielding meant less radiation was measured.

Caption Answer

Figure 18 A small amount of mass is converted into energy.

Debates and Discussions

Ask students to research the pros and cons of using nuclear energy. Then, engage the class in a discussion of the topic, encouraging students to take a position on the use of nuclear energy in the United States.

3 Assess

DAILY INTERVENTION

Check for Understanding

Visual-Spatial Have students draw a diagram of atoms undergoing nuclear fission and nuclear fusion. Students should label the reactants and products of each reaction, as well as the type of atom that is undergoing the process.

Reteach

Nuclear Reactors Have each student make a simple sketch of a nuclear reactor, showing the major parts of the reactor and describing the function of each of them. **L2** **IS** **Visual-Spatial** **P**

Assessment

Content Have students draw diagrams showing a nuclear fission chain reaction and how it is controlled in nuclear power plants. Use PASC, p. 163.

H-3 nucleus

He-4 nucleus

H-2 nucleus

Neutron

Figure 18 In nuclear fusion, two smaller nuclei join together to form a larger nucleus. Energy is released in the process. In the reaction shown here, two isotopes of hydrogen come together to form a helium nucleus.

Identify the source of the energy released in a fusion reaction.

Energy

Nuclear Fusion

The Sun gives off a tremendous amount of energy through a process called thermonuclear fusion. Thermonuclear fusion is the joining together of small nuclei at high temperatures, as shown in **Figure 18**. In this process, a small amount of mass is converted into energy. Fusion

is the most concentrated energy source known.

An advantage of producing energy using nuclear fusion is that the process uses hydrogen as fuel. Hydrogen is abundant on Earth. Another advantage is that the product of the reaction is helium. Helium is not radioactive and is chemically nonreactive.

One disadvantage of fusion is that it occurs only at temperatures of millions of degrees Celsius. Research reactors often consume more energy to reach and maintain these temperatures than they produce. Another problem is how to contain a reaction that occurs at such extreme conditions. Until solutions to these and other problems are found, the use of nuclear fusion as an energy source is not practical.

section 2 review

Summary

Using Nuclear Energy

- Nuclear power plants produce about eight percent of the energy used each year in the United States.

Nuclear Power Plants

- Nuclear reactors use the energy released in the fission of U-235 to produce electricity.
- The energy released in the fission reaction is used to make steam. The steam drives a turbine that rotates an electric generator.

The Risks of Nuclear Energy

- Organisms could be damaged if radiation is released from the reactor.
- Nuclear waste is the radioactive by-product produced by using radioactive materials.
- Nuclear power generation produces high-level nuclear wastes.

Self Check

1. **Explain** why a chain reaction occurs when uranium-235 undergoes fission.
2. **Describe** how the chain reaction in a nuclear reactor is controlled.
3. **Compare** the advantages and disadvantages of nuclear power plants and those that burn fossil fuels.
4. **Describe** the advantages and disadvantages of using nuclear fusion reactions as a source of energy.
5. **Think Critically** A research project produced 10 g of nuclear waste with a short half-life. How would you classify this waste, and how would it be disposed of?

Applying Math

6. **Use Percentages** Naturally occurring uranium contains 0.72 percent of the isotope uranium-235. What is the mass of uranium-235 in 2,000 kg of naturally-occurring uranium?

section 2 review

1. Neutrons are produced when U-235 undergoes decay. These neutrons are absorbed by other U-235 neutrons which release more neutrons when they decay.
2. Control rods are used to absorb excess neutrons.
3. Advantages: Nuclear power plants do not release air pollutants or carbon dioxide; Disadvantages: The mining of uranium can cause environmental damage. The possible escape of harmful radiation and the disposal of nuclear wastes are additional disadvantages of nuclear power generation.
4. Advantages: A small amount of mass is converted into a large amount of energy. Hydrogen is an abundant fuel source; Disadvantages: The reaction occurs at difficult-to-maintain temperatures. The extreme temperatures involved make the reaction hard to contain.
5. It is a low-level waste that should be sealed in an insulated container and buried in a repository.
6. 14.4 kg

Renewable Energy Sources

Reading Guide

What You'll Learn

- **Analyze** the need for alternate energy sources.
- **Describe** alternate methods for generating electricity.
- **Compare** the advantages and disadvantages of various alternate energy sources.

Why It's Important

Alternative energy sources need to be explored because the primary sources of energy used in the United States are nonrenewable.

Review Vocabulary

radiant energy: the energy carried by an electromagnetic wave

New Vocabulary

- renewable resource
- photovoltaic cell
- hydroelectricity
- geothermal energy
- biomass

Energy Options

The demand for energy continues to increase, but supplies of fossil fuels are decreasing. Using more nuclear reactors to produce electricity will produce more high-level nuclear waste that has to be disposed of safely. As a result, other sources of energy that can meet Earth's increasing energy demands are being developed. Some alternative energy sources are considered to be renewable resources. A **renewable resource** is an energy source that is replaced nearly as quickly as it is used.

Energy from the Sun

The average amount of solar energy that falls on the United States in one day is more than the total amount of energy used in the United States in one year. Because only about one billionth of the Sun's energy falls on Earth, and because the Sun is expected to continue producing energy for several billion years, solar energy cannot be used up. Solar energy is a renewable resource.

Many devices use solar energy for power including solar-powered calculators similar to the one in **Figure 19**. These devices use a **photovoltaic cell** that converts radiant energy from the Sun directly into electrical energy. Photovoltaic cells also are called solar cells.

Figure 19 This calculator uses a solar cell to produce the electricity it needs to operate.

IS Kinesthetic

Materials piece of cloth, watch or clock, water, scissors

Analysis

1. the cloth in direct sunlight
2. The energy absorbed from the Sun warms the cloth and makes the water evaporate quicker.

Assessment

Oral Ask students to identify the dependent and independent variables and the constants in this experiment. The dependent variable is drying time and the independent variable is location of the cloth. Constants include size, type, and initial dampness of the cloth.

Figure 20 Solar cells convert radiant energy from the Sun to electricity.

Identify two devices that use solar cells for power.

A solar cell is made of two layers of semiconductor material.

Using Solar Power at Home

Procedure

1. Cut a piece of cloth into two pieces about 10 cm on each side.
2. Wet both pieces and wring them out so they are equally damp.
3. Spread the pieces out to dry outside. One piece should be in sunlight and the other should be in shade.
4. Record the time it takes for each piece to dry.

Analysis

1. Which piece of cloth received more solar energy?
2. Explain why the drying time for a piece of cloth depends on the amount of solar energy it receives.

How Solar Cells Work Solar cells are made of two layers of semiconductor materials sandwiched between two layers of conducting metal, as shown in **Figure 20**. One layer of semiconductor is rich in electrons, while the other layer is electron poor. When sunlight strikes the surface of the solar cell, electrons flow through an electrical circuit from the electron-rich semiconductor to the electron-poor material. This process of converting radiant energy from the Sun directly to electrical energy is only about 7 percent to 11 percent efficient.

Using Solar Energy Producing large amounts of electrical energy using solar cells is more expensive than producing electrical energy using fossil fuels. However, in remote areas where electric distribution lines are not available, the use of solar cells is a practical way of providing electrical power.

Currently, the most promising solar technologies are those that concentrate the solar power into a receiver. One such system is called the parabolic trough. The trough focuses the sunlight on a tube that contains a heat-absorbing fluid such as synthetic oil or liquid salt. The heated fluid is circulated through a boiler where it generates steam to turn a turbine, generating electricity.

The world's largest concentrating solar power plant is located in the Mojave Desert in California. This facility consists of nine units that generate over 350 megawatts of power. These nine units can generate enough electrical power to meet the needs of approximately 500,000 people. These units use natural gas as a backup power source for generating electricity at night and on cloudy days when solar energy is unavailable.

Visual Learning

Figure 20 The semiconductor layers of this solar cell form a diode, a device that allows current to flow in only one direction. Thin metal strips on top of the cell serve as contacts for collecting the current. One advantage of solar cells is that they have no moving parts. Why does this make them attractive for use on satellites in space? Solar cells require no maintenance and no fuel.

Differentiated Instruction

Learning Disabled Have students bring in devices that use solar cells, such as toys and calculators. Show how the devices stop working if the solar cell's light source is blocked. **L1** **ELL** **IS** Visual-Spatial

Energy from Water

Just as the expansion of steam can turn an electric generator, rapidly moving water can as well. The gravitational potential energy of the water can be increased if the water is retained by a high dam. This potential energy is released when the water flows through tunnels near the base of the dam. **Figure 21** shows how the rushing water spins a turbine, which rotates the shaft of an electric generator to produce electricity. Dams built for this purpose are called hydroelectric dams.

Using Hydroelectricity Electricity produced from the energy of moving water is called **hydroelectricity**. Currently about 8 percent of the electrical energy used in the United States is produced by hydroelectric power plants. Hydroelectric power plants are an efficient way to produce electricity with almost no pollution. Because no exchange of heat is involved in producing steam to spin a turbine, hydroelectric power plants are almost twice as efficient as fossil fuel or nuclear power plants.

Reading Check Why are hydroelectric power plants more efficient than fossil fuel power plants?

Another advantage is that the bodies of water held back by dams can form lakes that can provide water for drinking and crop irrigation. These lakes also can be used for boating and swimming. Also, after the initial cost of building a dam and a power plant, the electricity is relatively cheap.

However, artificial dams can disturb the balance of natural ecosystems. Some species of fish that live in the ocean migrate back to the rivers in which they were hatched to breed. This migration can be blocked by dams, which causes a decline in the fish population. Fish ladders, such as those shown in **Figure 22**, have been designed to enable fish to migrate upstream past some dams. Also, some water sources suitable for a hydroelectric power plant are located far from the regions needing power.

Figure 21 The potential energy in water stored behind the dam is converted to electrical energy in a hydroelectric power plant.

Diagram the energy conversions that occur as a hydroelectric dam produces electrical energy.

Figure 22 Fish ladders enable fish to migrate upstream past dams.

SECTION 3 Renewable Energy Sources 503

Discussion

Water Use Water is a free and renewable resource. Why, then, doesn't it supply more of our energy needs? Most sites suitable for developing hydroelectric power are already in use. Hydroelectric plants cannot be built in other locations because they disrupt the natural ecosystems or the geography of the location does not make it practical. **L2** **IS** Logical-Mathematical

Caption Answer

Figure 21 The kinetic energy of falling water produces mechanical energy when it strikes and rotates the turbine. The turbine rotates a shaft of an electric generator that transforms mechanical energy to electrical energy.

IDENTIFYING

Misconceptions

Alternative Energy Sources

Students may think that because an alternative energy source isn't economical on a large scale that it isn't useful. Explain that many alternative energy sources, such as hydroelectricity, solar power, and wind power, are ideal for use on a small scale in rural areas or in developing societies.

Reading Check

Answer Hydroelectric power plants do not have a loss of energy converting thermal energy to mechanical energy. The falling water provides the mechanical energy required to turn the turbine to generate electricity.

Reading Strategy

Metacognitive Strategy Have students read the sections titled Energy from Water, Energy from the Tides, and Harnessing the Wind. As students read, ask them to notice where they struggle with comprehension. Engage the class in a discussion of how, where, and when comprehension breaks down.

Cultural Diversity

The Amish and Electricity The Amish in the United States avoid modern technology and focus on a simple life based on family, church, and community. Have students find out more about how the Amish use technology. Some Amish will use such things as telephones and cars without owning them. Some have their own electrical generators, but do not tap into public power supplies. **L3** **IS** Linguistic

Teacher FYI

Tidal Energy The Annapolis Royal tidal energy plant is located on the Bay of Fundy between New Brunswick and Nova Scotia in Canada, which has tides up to 17 meters high. These are the highest tides in the world. [L3]

Linguistic

Discussion

Tide Height Why do some coastal areas have higher tides than others? *The height of the tide is increased by geographical features, such as the shapes of bays and inlets and the slope of the ocean floor.*

Fun Fact

Tidal energy is possible only if the difference between high and low tides is more than 5 m. A higher tide difference means the plant can produce more electricity at a lower cost. A dam is needed to hold back the water at high tide. The dam's high construction cost makes it cheaper to build tidal plants on narrow inlets.

Quick Demo

Windmills

Materials toy pinwheel

Estimated Time five minutes

Procedure Use a toy pinwheel to demonstrate how a windmill works. Blow gently into the pinwheel forcing it to spin.

Figure 23 This tidal energy plant at Annapolis Royal, Nova Scotia, generates 20 megawatts of electric power.

that of a conventional hydroelectric power plant. However, only a few places on Earth have large enough differences between high and low tides for tidal energy to be a useful energy source. The only tidal power station in use in North America is at Annapolis Royal, Nova Scotia, shown in **Figure 23**. Tidal energy probably will be a limited source of energy in the future.

Harnessing the Wind

You might have seen a windmill on a farm or pictures of windmills in a book. These windmills use the energy of the wind to pump water. Windmills also can use the energy of the wind to generate electricity. Wind spins a propeller that is connected to an electric generator. Windmill farms, like the one shown in **Figure 24**, may contain several hundred windmills.

However, only a few places on Earth consistently have enough wind to rely on wind power to meet energy needs. Also, windmills are only about 20 percent efficient on average. Research is underway to improve the design of wind generators and increase their efficiency. Other disadvantages of wind energy are that windmills can be noisy and change the appearance of a landscape. Also, they can disrupt the migration patterns of some birds. However, wind generators do not consume any nonrenewable natural resources, and they do not pollute the atmosphere or water.

Teacher FYI

Tidal Power Plants The world's first and largest tidal power plant began operating in 1967 at the Rance River in France, with a capacity of 240 MW. The Annapolis Royal plant in Canada has a 20-MW capacity, and the tidal plant near Murmansk in Russia has a capacity of 0.4 MW.

Differentiated Instruction

English-Language Learners Have students create a poster showing different types of renewable energy sources. Have students find a real location or an example that uses each type of renewable energy to generate power. Include these examples on the poster. **P**

Energy from Inside Earth

Earth is not completely solid. Heat is generated within Earth by the decay of radioactive elements. This heat is called geothermal heat. Geothermal heat causes the rock beneath Earth's crust to soften and melt. This hot molten rock is called magma. The thermal energy that is contained in hot magma is called **geothermal energy**.

In some places, Earth's crust has cracks or thin spots that allow magma to rise near the surface. Active volcanoes, for example, permit hot gases and magma from deep within Earth to escape. Perhaps you have seen a geyser, like Old Faithful in Yellowstone National Park, shooting steam and hot water. The water that shoots from the geyser is heated by magma close to Earth's surface. In some areas, this hot water can be pumped into houses to provide heat.

Reading Check What two natural phenomena are caused by geothermal heat?

Geothermal Power Plants

Geothermal energy also can be used to generate electricity, as shown in **Figure 25**. Where magma is close to the surface, the surrounding rocks are also hot. A well is drilled and water is pumped into the ground, where it makes contact with the hot rock and changes into steam. The steam then returns to the surface, where it is used to rotate turbines that spin electric generators.

The efficiency of geothermal power plants is about 16 percent. Although geothermal power plants can release some gases containing sulfur compounds, pumping the water created by the condensed steam back into Earth can help reduce this pollution. However, the use of geothermal energy is limited to areas where magma is relatively close to the surface.

Scienceonline

Topic: Geothermal Energy

Visit fl.gpscience.com for Web links to information about geothermal energy.

Activity Using the information that you find, write a paragraph describing why geothermal power plants are located where they are.

Figure 25 A geothermal power plant converts geothermal energy to electrical energy.

Content Background

Most sources of geothermal energy are in areas with high volcanic activity. Geothermal energy is used on a large scale in Japan, Iceland, Italy, New Zealand, and California.

Discussion

Geothermal Energy Is geothermal energy renewable? Heat from a particular reservoir can be used up faster than it can be replaced, so it is not renewable. However, radioactive decay will provide a constant heat source for millions of years. **L3** **IS** Logical-Mathematical

Use Science Words

Word Meaning Why is heat from Earth called "geothermal"? *Geo* means "Earth," and *thermal* means "heat." **L2** **IS** Linguistic

Reading Check

Answer volcanoes and geysers

Visual Learning

Figure 25 In a geothermal plant such as the one shown here, after the steam has turned the turbine, the steam is condensed and returned to the rock through the injection well. Why is the water returned to the rock formation? to maintain the supply of water needed to produce steam **L2** **IS** Logical-Mathematical

Post Reading

Semantic Feature Analysis Have students list renewable energy sources across the top of a grid. Along the sides, they should list features the energy sources might possess. For example, they might list "can be burned to provide heat." To analyze the energy sources, students will write "+" if the feature is present, and "-" if it is not.

Differentiated Instruction

Challenge Have students research and write descriptions of the various forces that affect wind. They might write about the effects of temperature and pressure, surface obstacles, Earth's rotation, sea breezes, and mountain breezes. **L3** **IS** Logical-Mathematical

Discussion

Alternative Fuels Using biomass and other alternative fuels reduces dependence on foreign oil. Why is this desirable? **Political disagreements could reduce access to foreign oil because of strained relations with some countries.** L3 **Logical-Mathematical**

Figure 26 Hydrogen may one day replace gasoline as a fuel for automobiles. Burning hydrogen produces water vapor, instead of carbon dioxide.

Alternative Fuels

The use of fossil fuels would be greatly reduced if cars could run on other fuels or sources of energy. For example, cars have been developed that use electrical energy supplied by batteries as a power source. Hybrid cars use both electric motors and gasoline engines. Hydrogen gas is another possible alternative fuel. It produces only water vapor when it burns and creates no pollution. **Figure 26** shows a car that is equipped to use hydrogen as fuel.

Biomass Fuels Could any other materials be used to heat water and produce electricity like fossil fuels and nuclear fission? Biomass can be burned in the presence of oxygen to convert the stored chemical energy to thermal energy. **Biomass** is renewable organic matter, such as wood, sugarcane fibers, rice hulls, and animal manure. Converting biomass is probably the oldest use of natural resources for meeting human energy needs.

DAILY INTERVENTION

Check for Understanding

Interpersonal Have the students work in small groups. Each group should choose one of the energy sources discussed in the chapter. Have the students devise a plan describing how their chosen energy source could be used in their community.

Reteach

Renewable Energy Sources Ask students to list the six energy sources discussed in this section. Once the students have a complete list, ask them to write a sentence about each source, describing how it can be used to provide energy. L2

Linguistic

Assessment

Performance Have students work in small groups to design and create a system for heating water using solar power. Use PASC, p. 117.

section 3 review

Summary

Energy Options

- The development of alternative energy sources can help reduce the use of fossil fuels.

Solar Energy

- Photovoltaic cells, or solar cells, convert radiant energy from the Sun into electrical energy.
- Producing large amounts of energy from solar cells is more expensive than using fossil fuels.

Other Renewable Energy Sources

- Hydroelectric power plants convert the potential energy in water to electrical energy.
- Tidal energy, wind energy, and geothermal energy can be converted into electrical energy, but are useable only in certain locations.
- Alternative fuels such as hydrogen could be used to power cars, and biomass can be burned to provide heat.

Self Check

1. **Explain** the need to develop and use alternative energy sources.
2. **Describe** three ways that solar energy can be used.
3. **Explain** how the generation of electricity by hydroelectric, tidal, and wind sources are similar to each other.
4. **Explain** why geothermal energy is unlikely to become a major energy source.
5. **Think Critically** What single energy source do most energy alternatives depend on, either directly or indirectly?

Applying Math

6. **Use Percentages** A house uses solar cells that generate 6.0 kW of electrical power to supply some of its energy needs. If the solar panels supply the house with 40 percent of the power it needs, how much power does the house use?

section 3 review

1. The use of alternative energy sources can cause the use of fossil fuels to be reduced. This would make the supply of fossil fuels last longer, and reduce the emission of pollutants and carbon dioxide into the atmosphere.
2. Possible answers: Let the sun warm and light rooms. Use solar panels for heating water or air. Use photovoltaic cells to produce electricity.
3. They are all renewable sources. Each of these spins a turbine to rotate the shaft of an electric generator.
4. It is limited to areas where magma is relatively close to the surface.
5. the Sun
6. 15 kW

Solar Heating

Energy from the Sun is absorbed by Earth and makes its temperature warmer. In a similar way, solar energy also is absorbed by solar collectors to heat water and buildings.

Real-World Problem

Does the rate at which an object absorbs solar energy depend on the color of the object?

Goals

- **Demonstrate** solar heating.
- **Compare** the effectiveness of heating items of different colors.
- **Graph** your results.

Materials

small cardboard boxes
black, white, and colored paper
tape or glue
thermometer
watch with a second hand

Procedure

1. Cover at least three small boxes with colored paper. The colors should include black and white as well as at least one other color.
2. Copy the data table into your Science Journal. Replace *Other color* with whatever color you are using.
3. Place the three objects on a windowsill or other sunny spot and note the starting time.
4. **Measure and record** the temperature inside each box at 2-min intervals for at least 10 min.

Temperature Due to Different Colors

Color	2 min	4 min	6 min	8 min	10 min
Black	Student answers will vary.				
White					
Other color					

Conclude and Apply

1. **Graph** your data using a line graph.
2. **Describe** the shapes of the lines on your graph. What color heated up the fastest? Which heated up the slowest?
3. **Explain** why the colored boxes heated at different rates.
4. **Infer** Suppose you wanted to heat a tub of water using solar energy. Based on the results of this activity, what color would you want the tub to be? Explain.
5. **Explain** why you might want to wear a white or light-colored shirt on a hot, sunny, summer day.

Communicating Your Data

Compare your results with those of other students in your class. Discuss any differences found in your graphs, particularly if different colors were used by different groups.

Assessment

Content Have students make cartoons illustrating situations in which the color of something is important to its temperature. For example, dark-colored car seats are hotter in summer than those with a light color. Use **Performance Assessment in the Science Classroom**, p. 133.

Communicating Your Data

Have students use a computer graphing program to prepare their graphs. Encourage them to make their graphs as clear as possible so that others can understand the results easily. Remind students that a clear presentation of data is important to help others benefit from their work.

Video Lab available for this Lab.

Real-World Problem

Purpose Students demonstrate how various colors absorb solar energy differently and graph the results. **L2** **Kinesthetic**

Process Skills observe, infer, compare and contrast, recognize cause and effect, communicate, make and use tables, make and use graphs, interpret data

Time Required 45 minutes

Procedure

Teaching Strategy Suggest students work in pairs to make measurements. One student can read the thermometer as the other student fills in the data table. Have students work individually to prepare their graphs.

Troubleshooting Students should cover each box in a way that does not allow heat to escape.

Conclude and Apply

1. Suggest students use a different color line for each color of paper.
2. The lines all sloped upward. Black heated the fastest. White heated the slowest.
3. Black absorbs more light energy, which makes it heat faster, and white absorbs less light energy, which makes it heat more slowly.
4. Because black heats up faster, you would want the tub to be black.
5. You would want to wear a white or light-colored shirt because it absorbs less light energy and wouldn't heat up as quickly.

Real-World Problem

Purpose

Internet Students will use Internet sites that can be accessed by visiting fl.gpscience.com. They will investigate the costs and environmental impacts of different energy sources.

Non-Internet Sources Product information publications often have comparison data for energy sources such as batteries, as well as energy efficiency ratings for appliances.

Process Skills gather and organize information, evaluate sources of information, make and use tables, compare and contrast, evaluate, infer

Time Required about three days

Make a Plan

Preparation

Internet Visit fl.gpscience.com to run through the steps students will follow.

Non-Internet Sources Collect magazines and periodicals that list efficiencies of energy sources and appliances.

Follow Your Plan

Teaching Strategy Remind students that they should consider how different energy sources, such as rechargeable batteries and disposable batteries, affect the environment.

LAB

Use the Internet

How much does energy really co\$t?

Real-World Problem

You know that it costs money to produce energy. Using energy also can have an impact on the environment. For example, coal costs less than some other fuels. However, combustion is a chemical reaction that can produce pollutants, and burning coal produces more pollution than burning other fossil fuels, such as natural gas. Even energy sources, such as hydroelectric power, that don't produce pollution can have an impact on the environment. What are some of the environmental impacts of the energy sources used in the United States? How can these environmental impacts be compared to the cost of the energy produced?

Make a Plan

1. **Research** the various sources of energy used in different areas of the United States and choose three energy sources to investigate.
2. **Research** the cost of the consumer of 1 kWh of electrical energy generated by energy sources you have chosen.
3. **Determine** the effects each of the three energy sources has on the environment.
4. **Use** your data to create a table showing the energy sources, and the energy cost and environmental impact of each energy source.
5. **Decide** how you will evaluate the environmental impact of each of your energy sources.
6. **Write** a summary describing which of your three energy sources is the most cost-effective for producing energy. Consider the cost of the energy and your evaluation of the environmental impact in making your decision. Use information from your research to support your conclusions.

Goals

- **Identify** three energy sources that people use.
- **Determine** the cost of the energy produced by each source.
- **Describe** the environmental impact of each source.

Data Source

Internet Lab

Visit fl.gpscience.com for more information about energy sources and for data collected by other students.

Alternative Inquiry Lab

Real-World Connection To make this Lab an Inquiry Lab, give the students a more personal investment into the problem by connecting it to the real world. Divide the students into small groups. Each group will start a small imaginary manufacturing facility. The facility must be powered primarily by some type of renewable energy. At least 60 percent of the power for the

facility must come from an on-site renewable energy source. Have students investigate the types of energy sources available for their area. Students should develop a site plan for their facility that includes a site for their renewable energy source. This Lab will help students develop problem-solving skills, critical-thinking skills, and team-building skills.

Using Scientific Methods

Follow Your Plan

1. Make sure your teacher approves your plan before you start.
2. **Record** your data in your Science Journal.

Analyze Your Data

1. Of the energy sources you investigated, which is the most expensive to use? The least expensive?
2. Which energy source do you think has the most impact on the environment? The least impact?

Energy Sources

Energy Source	Cost per kWh	Environmental Impacts
Energy source 1	Student answers	
Energy source 2	will vary.	
Energy source 3		

Conclude and Apply

1. **Explain** Of the energy sources you investigated, which is the least expensive energy source? Which is the best choice to use? Why?
2. **Explain** Of the energy sources you investigated, how did the environmental impact of using that energy source influence your choice of the best energy solution?
3. **Evaluate** Which data support your decision?

Communicating Your Data

Find this lab using the link below.
Post your data in the table provided.
Compare your data to those of other students.

Internet Lab
fl.gpescience.com

Analyze Your Data

1. Answers may vary. Remind students to consider the costs of producing energy sources as they evaluate the cost of using each source.
2. Answers may vary. Students should evaluate different environmental impacts of energy sources, such as water pollution and pollutants released into the ground.

Conclude and Apply

1. To support their answers, ask students to provide specific facts to explain why an energy source is the least expensive or the most expensive and the best choice.
2. Student responses should describe how the chosen energy source affects the environment.
3. Information from scientific and energy industry sources may provide data to support students' hypotheses.

LAB 509

Assessment

Process Have students make displays describing their findings. Displays should include the items that were investigated, students' hypotheses, different energy sources that could be used to operate the items, and the cost and environmental impact of each energy source. Use **Performance Assessment in the Science Classroom**, p. 135.

Communicating Your Data

Have students design a rating system to evaluate the environmental impact of various energy sources. After analyzing each energy source for each criterion, students can make bar graphs representing their results.

Content Background

Nuclear energy is a complicated subject. Images of the devastation from atomic explosions and sensational accounts of the dangers of radiation have created fear regarding anything labeled *nuclear*. The abstract nature of the subject offers little comfort to the layman.

Radiation occurs when an unstable atom ejects particles or energy from its nucleus in the process of becoming stable. Fission, the splitting of an atom into two smaller atoms, releases neutrons. These neutrons collide with other nuclei, causing them to split and emit neutrons. This process can cause a chain reaction. Nuclear fission reactions can release high-energy electromagnetic radiation called gamma rays, which can only be blocked by lead or thick concrete.

Discussion

Drawbacks Are there any drawbacks to wind, hydroelectric, or tidal power technologies? *Possible answers:* Wind and tide generation are variable and restricted to a localized area. Hydroelectric power requires building dams, which then have an impact on wildlife habitats. Wind and hydro power use much more land area per kilowatt than the other sources of power.

Investigate the Issue

Have students research the feasibility of power sources not discussed in the article such as fusion and fuel cells. Discuss whether any of these might replace currently available sources.

Reacting to Nuclear Energy

Most people agree that thanks to energy sources, we have many things that make our quality of life better. Energy runs our cars, lights our homes, and powers our appliances. What many people don't agree on is where that energy should come from.

Almost all of the world's electric energy is produced by thermal power plants. Most of these plants burn fossil fuels—such as coal, oil, and natural gas—to produce energy. Nuclear energy is produced by fission, which is the splitting of an atom's nucleus. People in favor of nuclear energy argue that, unlike fossil fuels, nuclear energy is nonpolluting.

Opponents counter, though, that the poisonous radioactive waste created in nuclear reactors qualifies as pollution—and will be lingering in the ground and water for hundreds of thousands of years.

Supporters of nuclear energy also cite the spectacular efficiency of nuclear energy—one metric ton of nuclear fuel produces the same amount of energy as up to 3 million tons of coal. Opponents point out that uranium is in very short supply and, like fossil fuels, is likely to run out in the next 100 years.

Opponents worry that as utilities come under less government regulation, safety standards will be ignored in the interest of profit.

This could result in more accidents like the one that occurred at Chernobyl in the Ukraine. There, an explosion in the reactor core released radiation over a wide area.

Supporters counter that it will never be in the best interests of those running nuclear plants to relax safety standards since those safety standards are the best safeguard of workers' health. They cite the overall good safety record of nuclear power plants.

This site at Yucca Mountain, Nevada, is the location of a proposed high-level nuclear waste storage facility. Here, radioactive materials would be buried for tens of thousands of years.

Debate Form three teams and have each team defend one of the views presented here. If you need more information, go to the link at the right. “Debrief” after the debate. Did the arguments change your understanding of the issues?

TIME

For more information, visit
fl.gpscience.com

Debate Have the teams use the knowledge they gained from the activity and investigation above to help them investigate the cost per kilowatt of one of the technologies discussed. Remind students to keep in mind the amount and type of pollution caused by each technology and by processing its fuel. Ask teams for recommendations about future energy production.

Quarks and Sparks: The Story of Nuclear Power (Science and Society Series), by J. S. Kidd and Renee A. Kidd, New York: Facts on File (1999)

American Wind Energy Association, 122 C Street, NW, Suite 380, Washington, DC 20001

Reviewing Main Ideas

Section 1 Fossil Fuels

1. Fossil fuels include oil, natural gas, and coal. They formed from the buried remains of plants and animals.
2. Fossil fuels can be burned to supply energy for generating electricity. Petroleum also is used to make plastics and synthetic fabrics.
3. Fossil fuels are nonrenewable energy resources. They can be replaced, but it takes millions of years.

Section 2 Nuclear Energy

1. A nuclear reactor transforms the nuclear energy from a controlled nuclear chain reaction into electrical energy.
2. Nuclear wastes must be contained and disposed of carefully so radiation from nuclear decay will not leak into the environment. These low-level nuclear wastes are buried to protect living organisms.

3. Nuclear fusion releases energy when two nuclei combine. Fusion only occurs at high temperatures that are difficult to produce in a laboratory.

Section 3 Renewable Energy Sources

1. Alternative energy resources can be used to supplement or replace nonrenewable energy resources.
2. Other sources of energy for generating electricity include hydroelectricity and solar, wind, tidal, and geothermal energy. Each source has its advantages and disadvantages. Also, some of these sources can damage the environment.
3. Although some alternative energy sources produce less pollution than fossil fuels do and are renewable, their use often is limited to the regions where the energy source is available. For example, tides can be used to generate electricity in coastal regions only.
4. It may be possible to use hydrogen as a fuel for automobiles and other vehicles. Biomass, such as wood and other renewable organic matter, has been used as fuel for thousands of years.

FOLDABLES Use the Foldable that you made at the beginning of the chapter to help you review energy sources.

Assessment Transparency

For additional assessment questions, use the *Assessment Transparency* located in the transparency book.

Assessment

Energy Sources			
Group A		Group B	
Energy	Percent of energy consumed in U.S.	Energy	Percent of energy consumed in U.S.
Coal	23%	Hydroelectric	3%
Natural gas	23%	Wind	less than 1%
Petroleum	39%	Solar	less than 1%
Nuclear	8%	Geothermal	less than 1%
		Biomass	less than 1%

Directions: Carefully review the tables and answer the following questions.

1. The energy sources in Group A are different from the energy sources in Group B because the energy sources in Group B are _____.
 A. renewable resources C. fossil fuels
 B. nonrenewable resources D. harmful to the environment
2. According to the tables, which energy source supplies greater than 25% of the energy consumed in the U.S.?
 F. Coal H. Nuclear
 G. Hydroelectric J. Petroleum
3. According to the tables, what percent of the energy used in the U.S. comes from fossil fuels?
 A. 50% C. 85%
 B. 60% D. 93%

FOLDABLES

Have students use their Foldables to review the content of the chapter. On the back of the paper, have the students write the advantages and disadvantages of each type of energy source that is listed on the Foldable.

SC.B.1.4.5

Using Vocabulary

biomass p. 487	nuclear reactor p. 494
fossil fuel p. 487	nuclear waste p. 498
geothermal energy p. 503	petroleum p. 489
hydroelectricity p. 503	photovoltaic cell p. 501
nonrenewable resource p. 487	renewable resource p. 501

Complete each statement using a term from the vocabulary list above.

1. A(n) _____ uses the Sun to generate electricity.
2. _____ makes use of thermal energy inside the Earth.
3. Energy produced by the rise and fall of ocean levels is a(n) _____.
4. _____ includes the following: oil, natural gas, and coal.
5. Fossil fuels are a(n) _____ because they are being used up faster than they are being made.
6. A special caution should be taken in disposing of _____.

Checking Concepts

Choose the word or phrase that best answers the question.

7. Why are fossil fuels considered to be nonrenewable resources?
 - A) They are no longer being produced.
 - B) They are in short supply.
 - C) They are not being produced as fast as they're being used.
 - D) They contain hydrocarbons.
8. To generate electricity, nuclear power plants produce which of the following?
 - A) steam
 - B) carbon dioxide
 - C) plutonium
 - D) water

9. What is a major disadvantage of using nuclear fusion reactors?
 - A) use of hydrogen as fuel
 - B) less radioactivity produced
 - C) extremely high temperatures required
 - D) use of only small nuclei
10. How are spent nuclear fuel rods usually disposed of?
 - A) burying them in a community landfill
 - B) storing them in a deep pool of water
 - C) burying them at the reactor site
 - D) releasing them into the air

Use the graph below to answer question 11.

Sources of Energy

11. How much energy in the United States comes from burning fossil fuels?
 - A) 85%
 - B) 35%
 - C) 65%
 - D) 25%
12. What do hydrocarbons react with when fossil fuels are burned?
 - A) carbon dioxide
 - B) carbon monoxide
 - C) oxygen
 - D) water
13. Which of the following is NOT a source of nuclear waste?
 - A) products of fission reactors
 - B) materials with short half-lives
 - C) some medical and industrial products
 - D) products of coal-burning power plants
14. Which of the following is the source of almost all of Earth's energy resources?
 - A) plants
 - B) the Sun
 - C) magma
 - D) fossil fuels

Interpreting Graphics

15. Copy and complete the table below describing possible effects of changes in the normal operation of a nuclear reactor.

Reactor Problems

Cause	Effect
The cooling water is released hot.	Pollution of the environment results.
The control rods are removed.	More heat is produced in the core.
The cooling system fails.	The reactor core overheats and meltdown occurs.

16. Copy and complete this concept map.

Thinking Critically

17. **Infer** why alternative energy resources aren't more widely used.
18. **Infer** whether fossil fuels should be conserved if renewable energy sources are being developed.

19. **Infer** Suppose new reserves of fossil fuels were found and a way to burn these fuels was developed that did not release pollutants and carbon dioxide into the atmosphere. Should fossil fuels still be conserved? Explain
20. **Explain** why coal is considered a nonrenewable energy source, but biomass, such as wood, is considered a renewable energy source.
21. **Make a table** listing two advantages and two disadvantages for each of the following energy sources: fossil fuels, hydroelectricity, wind turbines, nuclear fission, solar cells, and geothermal energy.

Applying Math

22. **Convert Units** Crude oil is sold on the world market in units called barrels. A barrel of crude oil contains 42 gallons. If 1 gallon is 3.8 liters, how many liters are there in a barrel of crude oil?

Use the table below to answer question 25.

High-Production Coal Mines

Coal Mine	Metric tons/year
North Antelope Rochelle	6.78×10^7
Black Thunder	6.13×10^7

23. **Use Percentages** Nine of the top coal producing mines are located in Wyoming. Production information on two of the mines is in the table above. A total of about 1.02×10^9 metric tons is produced per year in the United States. What percentage do these two coal mines contribute to the total yearly coal production in the U.S.?

Interpreting Graphics

15. See student page.
16. See student page.

Thinking Critically

17. Alternative energy resources are not widely used because the necessary technology does not yet exist, is too expensive, or has limited applicability.
18. Fossil fuels should be conserved because they are used to produce useful materials, such as plastic.
19. These new sources would still be nonrenewable energy sources. Conserving fossil fuel would make them last longer.
20. Biomass can be replaced in several years by replanting. Coal takes millions of years to form.
21. Fossil fuels: inexpensive and plentiful, but are nonrenewable and produce pollutants. Hydroelectricity: renewable and inexpensive, but can affect local ecosystems and has limited availability. Wind turbines: nonpolluting and use a renewable energy source, but are noisy and have limited availability. Nuclear power: nonpolluting and inexpensive, but problems exist with nuclear waste disposal, and risks of nuclear accidents. Solar cells: use a renewable resource that is available everywhere, but inefficient and expensive. Geothermal energy: uses Earth's heat as a renewable resource and does not produce carbon dioxide, but is inefficient and has limited availability.

Applying Math

Math Standards

National: 1,5,9

Florida: MA.1.4.4, MA.B.2.4.2

22. $\frac{42 \text{ gallons}}{1 \text{ barrel}} \times \frac{3.8 \text{ liters}}{1 \text{ gallon}} = 159.6 \frac{\text{liters}}{\text{barrel}} = 160 \frac{\text{liters}}{\text{barrel}}$
23. $\frac{1.291 \times 10^8 \text{ metric tons/year}}{1.02 \times 10^9 \text{ metric tons/year}} = 0.127 = 12.7\%$

1. D
2. B
3. A
4. A
5. B

Record your answers on the answer sheet provided by your teacher or on a sheet of paper. The assessed Florida Benchmark appears above the question.

Multiple Choice

Use the graph below to answer questions 1 and 2.

Sources of Electricity

1. The graph above shows the percentage of electricity generated in the United States that comes from various energy sources. According to the graph, about what percentage comes from fossil fuels?
 - A. 51%
 - B. 55%
 - C. 65%
 - D. 69%
2. The graph shows that approximately what percentage of electricity comes from nonrenewable energy sources?
 - A. 97%
 - B. 89%
 - C. 69%
 - D. 55%

3. Which of the following is a typical efficiency for a solar cell?
 - A. 10%
 - B. 50%
 - C. 75%
 - D. 95%
4. Which of the following forms only from ancient plant material, not from ancient animal remains?
 - A. coal
 - B. crude oil
 - C. natural gas
 - D. petroleum

Use the table below to answer questions 5 and 6.

Efficiency of Fossil-fuel Conversion	
Process	Efficiency (%)
Chemical to thermal energy	60
Conversion of water to steam	90
Steam spins turbine	75
Turbine spins electric generator	95
Transmission through power lines	90

5C.B.1.4.7

5. The table above shows the efficiency of different steps in the conversion of fossil fuels to electricity at a power plant. According to the table, what is the efficiency for converting chemical energy in the fossil fuels to thermal energy, and then converting water to steam?
 - A. 40%
 - B. 54%
 - C. 25%
 - D. 90%

Gridded Response

SC.8.14.7

6. What is the overall efficiency shown in the table for converting chemical energy in fossil fuels to electricity?

Short Response

Use the illustration below to answer question 7.

7. Describe the purpose of the control rods and explain how their placement in the reactor affects the nuclear chain reaction.

SC.8.14.8

8. Fusion is the most concentrated energy source known. Why, then, is it not used at nuclear plants to make electricity?

Extended Response

Use the illustration below to answer question 9.

9. The illustration above shows a nuclear power plant that generates electricity using the energy released in nuclear fission of uranium-235. Draw a sketch showing this fission process. Describe your sketch and explain how the process results in a chain reaction.

SC.8.14.9

10. Describe two advantages and two disadvantages of using fossil fuels as a source of energy.

Test-Taking Tip

Determine the Information Needed Concentrate on what the question is asking about a table, instead of all the information in the table.

Question 5 Read the question carefully to determine which rows in the table contain the information needed to answer the question.

Gridded Response

6. 35

Short Response

7. to stop or slow the nuclear chain reaction by absorbing neutrons released during the reaction; Moving these control rods deeper into the reactor allows them to absorb more neutrons and slow down the reaction.
8. Fusion reactions occur only at temperatures of millions of degrees Celsius. Creating and maintaining these high temperatures requires enormous amounts of energy.

Extended Response

9. Use **Figure 14** to check students' sketches.
10. Advantages: relatively inexpensive and easy to transport from place to place.
Disadvantages: causes pollution and nonrenewable.

Rubrics

For more help evaluating Short- and Extended-Response questions, see the rubric on p. 9T.

Section/Objectives	Standards		Lab/Features
Chapter Opener	National	State/Local	Launch Lab: Atmospheric Pressure, p. 517 Foldables, p. 517
	See pp. 16T–17T for a Key to Standards.		
Section 1 Earth's Atmosphere  2 sessions  1 block 1. Describe the composition of the atmosphere. 2. Explain how the atmosphere is heated and include the role of land surface and water. 3. Describe Earth's system of water cycling.	National Content Standards: UCP.1–3, UCP.5, A.1, A.2, C.6, D.1, D.2	Florida Benchmarks: SC.A.1.4.4, SC.D.1.4.4, SC.G.1.4.3	MiniLAB: Visualizing Convection, p. 519  Video Lab Integrate Life Science, p. 522 Lab, Visualizing a Temperature Inversion, p. 523
Section 2 Weather  1 session  1.5 blocks 4. Explain what causes Earth's major wind and pressure systems. 5. Describe typical daily weather patterns around lows and fronts. 6. Describe the most important storm systems and forms of severe weather.	National Content Standards: UCP.1–3, UCP.5, A.1, A.2, D.1, D.2, B.4, B.6, D.1, D.2	Florida Benchmarks: SC.D.1.4.1	MiniLAB: Modeling the Coriolis Effect, p. 525 Science Online, p. 528
Section 3 Climate  1 session  1.5 blocks 7. Describe what determines climate. 8. Explain how latitude, oceans, and other factors affect the climate of a region. 9. Classify climate systems. 10. Describe climate distribution over the United States.	National Content Standards: UCP.1–3, UCP.5, A.1, A.2, B.4, B.6, C.5, D.1	Florida Benchmarks: SC.B.1.4.1, SC.D.1.4.3, SC.D.1.4.4, SC.D.2.4.1, SC.F.2.4.3, SC.G.1.4.1, SC.H.2.4.1	Science Online, p. 530 Visualizing Earth's Biogeophysical System, p. 531
Section 4 Earth's Changing Climates  3 sessions  1.5 blocks 11. Explain how climate changes seasonally. 12. Explain causes of climate change. 13. Describe how we influence climate. 14. Describe El Niño's effect on weather. Transparencies

Section Focus

Section Focus Transparency Satellite View of Earth **Chapter 17**

1. View Earth from space and label the tropics and stratosphere.

2. If you were to draw a circle around the diagram to show the tropics, where would the circle be?

3. Where is the stratosphere located in this picture?

Section Focus Transparency Sea Breeze **Chapter 17**

1. How does the temperature of the land compare with the temperature of the sea during the night and day?

2. What happens to the air over land during the day?

3. What happens to the air over the sea during the day?

4. What direction does the wind blow, and on the surface at night and at day?

Section Focus Transparency Desert Climate **Chapter 17**

1. What kind of climate does this photograph show?

2. What other kinds of climates exist on Earth?

3. What are some of the factors that determine a region's climate?

Section Focus Transparency Holgate Glacier **Chapter 17**

1. What will happen to the sea level if glaciers melt?

2. What are some of the causes of global warming?

3. How is global warming affecting the glaciers, and what are some of the effects of global warming on the environment?

This is a representation of key blackline masters available in the Teacher Classroom Resources. See Resource Manager boxes within the chapter for additional information.

Key to Teaching Strategies

The following designations will help you decide which activities are appropriate for your students.

- L1** Level 1 activities should be appropriate for students with learning difficulties.
- L2** Level 2 activities should be within the ability range of all students.
- L3** Level 3 activities are designed for above-average students.
- ELL** ELL activities should be within the ability range of English Language Learners.

COOP LEARN Cooperative Learning activities are designed for small group work.

MS Multiple Learning Styles logos, as described on page 12T, are used throughout to indicate strategies that address different learning styles.

P These strategies represent student products that can be placed into a best-work portfolio.

PBL Problem-Based Learning activities apply real-world situations to learning.

Assessment

Assessment Transparency Weather and Climate **Chapter 17**

1. The warmest month in Valdivia is January, July.

2. In April the average temperature is 18°C (64°F) in Beijing.

3. The average annual temperature in Beijing is approximately 12°C (54°F).

4. The average annual temperature in Valdivia is approximately 12°C (54°F).

5. If the temperature is 24°C, the temperature in degrees Fahrenheit is 75°F.

6. Valdivia is located in the southern, northern hemisphere.

7. The city where the temperature changes most rapidly from month to month is Valdivia, Beijing.

8. The city where the mildest temperature is Valdivia, Beijing.

9. Judging from the temperature alone, the city more likely to be near an ocean is Valdivia, Beijing.

The atmosphere is important for life on Earth because it provides the oxygen that we need to breathe. 4. It also helps to regulate the Earth's temperature by trapping heat from the sun. 5. This process is called the greenhouse effect. 6. The atmosphere also protects the Earth from harmful solar radiation. 7. Without the atmosphere, life as we know it would not be possible.		

Science Content Background

section 1 Earth's Atmosphere

1

Atmospheric Layers

Earth's atmosphere can be divided into distinct layers based on differences in temperature. The troposphere extends from the surface to an altitude of about 10 km. Temperatures in the troposphere generally decrease with height. The stratosphere extends from roughly 10 km above the surface to 50 km. Temperatures here increase with height. The mesosphere is located between 50 km and 90 km above Earth's surface. Here, temperatures again decrease with altitude. Above the mesosphere lies the thermosphere, which extends into space. Temperatures in the

thermosphere are high. However, because there are so few air molecules present at this altitude, the air would not feel warm.

section 2

Weather

Heat Transfer

Energy from the Sun powers global winds and creates the unequal heating of Earth's surface that results in weather. Solar energy is transferred throughout the atmosphere in four different ways. Radiation involves the transfer of energy by electromagnetic radiation, which includes visible light. Sunshine is an example of energy transfer by radiation. Conduction involves the transfer of energy that occurs when molecules collide. In this process, the Sun warms the ground. Heat from the ground is transferred by conduction to the layer of air nearest the surface. Convection involves the transfer of energy by the flow of a heated substance. In the atmosphere, convection plays a role in creating global wind patterns, local winds, and certain types of severe weather. The Sun's energy is also transferred to the atmosphere by latent heat. Solar radiation heats liquid water and converts it into vapor. This stored energy is released when water vapor condenses as precipitation. Water heats and cools slowly. For this reason large bodies of water have a moderating effect on climate.

Meteorology Today, Fifth Edition, by C. Donald Ahrens, West Publishing Company, 1994

Climate

Climatic Data

Climate normals represent standard climatic data for a given location.

These data might include high and low temperatures, rainfall amounts, wind speed and direction, and air pressure. Often, the normals include daily, monthly, and yearly mean values. The mean daily temperature, for example, is the average of the highest and lowest temperature within a 24-hour period. The mean monthly temperature is the average of mean daily temperatures over a 30-day period. Likewise, the mean yearly temperature is the average of mean monthly temperatures over 12 months. An area's annual temperature range is simply the difference between the mean temperatures of the warmest and coldest months.

Earth's Changing Climates

Global Warming

Scientists estimate that Earth's climate may have been as much as 15°C warmer during much of the planet's history. These warm periods of geologic time were interspersed with periods of glaciation, known as ice ages.

Ice ages occur in cycles lasting millions of years. At the peaks, the poles are covered with thick ice, glaciers advance into the mid latitudes, and sea levels fall. Between glaciations, Earth warms, the glaciers retreat, and sea levels rise. The last ice age peaked about 18,000 years ago when falling sea levels exposed land- bridges between England and Europe and between Asia and North America that may have allowed humans and animals to migrate.

Teacher to Teacher

Tracey L. Smeltzer
Library Specialist
Derry Area High School
Derry, PA

"After discussing atmospheric pressure, have students speculate about the effects that altitude has on an open carbonated beverage. For example, will an opened container remain carbonated longer in Denver, Colorado or Acapulco, Mexico? Ask students to support their ideas."

Tracey L. Smeltzer

Currently, Earth is warming again as would be expected based on glaciation cycles. However, the rate of warming has accelerated over the last century, raising concern that human activities, such as burning of fossil fuels, may be interfering with natural cycles. The term *global warming* refers these concerns.

To what degree human activities have interfered with natural cycles is unclear. Most scientists agree that increased greenhouse gases contribute greatly to global warming. However, they cannot identify this as the sole cause. The complexity of the interactions among Earth's systems makes it difficult to predict the effect of changing any one variable. A model must consider the effects of warming on ocean currents and levels, cloud formation, and rainfall distribution, and at the same time consider contributions from other sources, such as glaciation and volcanoes. Meanwhile, scientists continue to collect information and discuss the problem.

Lab Investigating Microclimate

Flash Flood!

When cool, dry air meets warm, moist air dramatic things can happen. Many desert environments are familiar with flash floods that can result from such an event. Dry river beds can suddenly become raging torrents of water, rocks, and mud.

Science Journal In your Science Journal, describe some of your observations of severe weather. Hypothesize what might cause these weather events.

516

Theme Connection

Change and Constancy The state of the atmosphere is in constant flux, as weather factors such as temperature and pressure vary day by day or hour by hour. Climates may also change; however, these changes usually occur in long-term cycles.

About the Photo

Storm in the Desert This photo shows a lightning storm over an Arizona desert. When relative humidity is very low, rain can fall from clouds and evaporate before it hits the ground. However, during a heavy rain, dry gulches or arroyos can fill rapidly with raging torrents of water and sediment.

Start-Up Activities

Atmospheric Pressure

Changes in atmospheric pressure are involved in producing winds and weather. You may not be aware of how much pressure the atmosphere exerts, but you can see it in this Lab.

1. Fill a glass to the brim with water.
2. Place a piece of thick paper or cardboard on top.
3. Hold the paper or cardboard securely to the brim of the glass. Turn the glass upside down.
4. Release your hand from the paper.
5. **Think Critically** What keeps the paper or cardboard against the brim of the glass and the water from flowing out?

Scienceonline

Preview this chapter's content and activities at fl.esc.nv.com

FOLDABLES™ Study Organizer

Weather and Climate Make the following Foldable to compare and contrast the characteristics of weather and climate.

STEP 1 Fold one sheet of paper lengthwise.

STEP 2 Fold into thirds.

STEP 3 Unfold and draw overlapping ovals. Cut the top sheet along the folds.

STEP 4 Label the ovals as shown.

Constructing a Venn Diagram As you read the chapter, list the characteristics unique to weather under the left tab, those unique to climate under the right tab, and those elements common to both under the middle tab.

Purpose Use this Launch Lab to introduce students to atmospheric pressure. [L2]

Materials water, glass, piece of thick paper or cardboard

Teaching Strategy Remind students that air exerts pressure in all directions. Have students take turns performing the Lab at the sink.

Think Critically

the pressure of the atmosphere against the paper or cardboard

Assessment

Performance Have students use a balloon and a balance to determine if air has mass. Students can find the mass of a deflated balloon. Then they can blow up the balloon and find its mass. Students should note that the increase in mass of the inflated balloon corresponds to the mass of the air.

FOLDABLES™ Study Organizer

**Dinah Zike
Study Fold**

Student preparation materials for this Foldable are available in the Chapter **FAST FILE** Resources.

Earth's Atmosphere

Section Focus Transparencies also are available on the Interactive Chalkboard CD-ROM.

Reading Preview

Tie to Prior Knowledge

Clouds Have students describe different cloud shapes they have seen in the sky. Tell students that in this section, they will learn how clouds form and take the shapes they do. L2

Word Map Have students divide a sheet of paper into quadrants and then write a new vocabulary word in the center. In the upper left have students write a definition in their own words; in the upper right have them write an example of the term; in the lower left have them write a sentence using the word; in the lower right have them draw a picture depicting the word.

Reading Guide

What You'll Learn

- **Describe** the composition of the atmosphere.
- **Explain** how the atmosphere is heated and include the role of land surface and water.
- **Describe** Earth's system of water cycling.

Why It's Important

Heat and water are essential for life on Earth.

Review Vocabulary

nucleus: a central point about which concentration or accretion takes place

New Vocabulary

- troposphere
- temperature inversion
- greenhouse effect
- latent heat

Atmospheric Composition

You probably never think about the air you breathe. Your body uses only oxygen, but air is a mixture of gases. Nitrogen is the largest component with 78 percent and oxygen is next with 21 percent by volume. Most of the remaining one percent is the inactive gas argon and water vapor in varying amounts. The small remaining portion is a mixture of trace gases, so called because they are present in such small, barely detectable amounts. For example, carbon dioxide makes up only about 0.03 percent, and the other trace gases—methane, nitrous oxide, and ozone—together make up less than 0.001 percent of the atmosphere. Still, these trace gases are critical for life on Earth.

Reading Check

What are the trace gases?

Figure 1 In northern latitudes, carbon dioxide concentration increases during summer and decreases during winter.

Biological Processes Living organisms produce trace gases, except ozone. Cellular respiration by organisms produces water vapor and carbon dioxide (CO₂). Photosynthetic organisms use carbon dioxide and produce almost all the oxygen in the atmosphere. Organisms alter atmospheric CO₂ concentration at various latitudes throughout the year, as shown in **Figure 1**. Microorganisms in swamps, rice paddies, and soil produce nitrogen and methane. The microorganisms in the digestive tracts of animals such as termites, cows, and sheep produce methane.

Reading Check

Answer gases that are found in very small amounts in the atmosphere, including carbon dioxide, methane, nitrous oxide, and ozone

Video Lab available.

Purpose Students will model convection.

Materials water, dropper, food coloring, beaker, ice cube

Preparation If only gel colors are available, add a few drops of water and mix well before giving to students.

Teaching Strategy Remind students that molecules move faster at higher temperatures. Hold a lighted candle near one of the student's beakers and ask them to observe the effect.

Analysis

1. The color should drop to the bottom, spread out, and then move up the sides of the beaker.
2. Movement of the coloring was caused by convection. The coloring near the ice cooled, became denser, and sank. Away from the ice, the coloring warmed, became less dense, and rose.

Assessment

Oral In their own words, have students summarize how air temperature changes with height in the troposphere and explain where convection has the greatest effect. In the troposphere, air temperature decreases with height. Convection is most effective in the lower troposphere closer to the surface. L2

Caption Answer

Figure 2 stratosphere

Visualizing Convection

Procedure

1. Place an ice cube in the center of a beaker.
2. Add room-temperature water until the beaker is three-fourths full.
3. Place one drop of food coloring on the surface of the water.
4. Observe what happens.

Analysis

1. Describe what happened to the color.
2. Explain why this occurred.

SECTION 1 Earth's Atmosphere 519

Teacher FYI

Air Pollution Temperature inversions are particularly harmful in urban areas, which are plagued by air pollution. A temperature inversion can trap the pollution over a city for days. In December 1952, for example, a

temperature inversion in London lasted one week. Pollutants from coal-burning factories and homes were trapped over the city. The air pollution trapped by the inversion caused the deaths of 4,000 people.

Discussion

The Greenhouse Effect Have students discuss how the greenhouse effect received its name. Point out that the greenhouse effect works much like a greenhouse. Have students explain the connection. *The greenhouse effect traps heat on Earth just as a greenhouse traps heat within its walls.* [L2]

Use Science Words

Word Meaning Have students use dictionaries to look up the meaning of the word *latent*. *present or potential, but not active* Have them relate the definition to the concept of latent heat. *Latent heat is stored energy that is present, but not yet active, in the atmosphere.* [L1] [ELL]

Quick Demo

Rates of Absorption

Materials two cake pans, soil, water, two thermometers, lamp

Estimated Time 25 minutes

Procedure Fill a cake pan with water at room temperature. Fill the second pan with soil. Have students observe while you record the temperature of the water and soil. Place the lamp over the pans. Turn on the lamp and let it shine on the pans for 20 min. Take the temperature of the water and soil. Students should see that the water heated more slowly than the soil.

Motivated students might expand this activity by measuring the temperature increases of the two materials at intervals and graphing the results. [L2] [ELL] [AS]

Caption Answer

Figure 3 A blanket traps a person's body heat, keeping the person warm.

Heating the Atmosphere

The energy that heats the atmosphere ultimately comes from the Sun. In the stratosphere, solar rays split oxygen molecules into single atoms. The oxygen atoms then react with other oxygen molecules, forming ozone. Ozone absorbs nearly all of the Sun's ultraviolet radiation. This absorption by ozone is why temperature increases with height in the stratosphere.

The remaining solar rays pass to Earth's surface where they are either absorbed or reflected back to the atmosphere. As Earth's surface is heated, it emits long-wave, infrared radiation. Trace gases, such as carbon dioxide and water vapor, absorb long wavelengths and re-emit some of them back to Earth's surface. The term **greenhouse effect** refers to this re-emission of infrared radiation back to Earth's surface, as shown in **Figure 3**.

Oxygen and nitrogen absorb little radiation and contribute little to atmospheric heating. Although water vapor and trace gases make up less than 0.03 percent of the atmosphere, they are strong absorbers and heat the atmosphere the most.

Conduction, convection, and latent heat also contribute to heating Earth's atmosphere. **Latent heat** is heat energy released or absorbed during the phase changes of water, such as evaporating water or melting snow. It is released to the atmosphere when water vapor condenses as clouds.

A Varied Surface

Earth's surface is not uniform and therefore, heats the atmosphere unevenly. Snow, ice, water, vegetation, and bare soil reflect different amounts of solar radiation back to space and heat at different rates when they absorb radiation. For example, dry land heats rapidly and emits much radiation to the atmosphere. In contrast, water temperature changes slowly and stores heat, releasing it at a later time. This uneven pattern of surface heating gives rise to pressure differences and wind.

Figure 3 Trace gases absorb infrared radiation and are heated. These gases then re-emit infrared in all directions, sending part of it back to Earth's surface.

Infer How does this compare to being covered by a blanket at night?

520 CHAPTER 17 Weather and Climate

Visual Learning

Figure 3 Ask students to compare the diagram to what they know about greenhouses used for growing plants. Ask them about similarities and differences. [L2] [ELL]

Fun Fact

Weather data are gathered by two different types of satellites. A geostationary satellite orbits at the same speed as Earth spins, so it remains above a fixed point. This allows the satellite to continually study one area. A polar-orbiting satellite orbits the poles. With each orbit of the satellite, Earth has rotated slightly, allowing the satellite to monitor different areas.

Water in the Atmosphere

Uneven heating has another effect. It produces currents of air that carry water vapor aloft and form clouds. Air generally rises over warm surfaces and sinks over cold surfaces. Many birds and hang gliders soar on these warm currents, called thermals.

As air rises, it expands and cools. To form clouds, moist air must rise high enough to cool to its dew point. At this temperature, air is saturated and water vapor condenses to form cloud droplets. Small particles in the air, called condensation nuclei, trigger this process. When present in high quantities, such as in dust or polluted city air, these nuclei can trigger condensation in unsaturated air. This is how smog forms.

Reading Check Explain how smog forms.

Precipitation Cloud formation is the first step in the precipitation process. Two basic cloud types are the puffy cumulus type and the flat, elongated, stratus type. Cumulus clouds form from rising air parcels. If they produce rain, it is usually only brief showers. Stratus-type clouds form mainly when layers of air rise gently. They usually produce drizzle or long-lasting rain. Many in-between forms of clouds exist, depending on how stable the air is and how high in the atmosphere the clouds form. You can see some of these types in **Figure 4**. One type you might recognize is the cumulonimbus, or thunderhead. This cloud forms from unstable air and usually brings intense rain.

Cloud droplets are so small that they might be kept aloft by turbulence or evaporate before reaching Earth. For precipitation to occur, droplets must grow large. Growth can occur when droplets collide and combine. This is called warm rain. Droplets grow faster when they combine with ice crystals high in the atmosphere. This is called cold rain.

High Clouds		Height
Cirrus		12 km
Cirrocumulus		(about 40,000 ft)
Cirrostratus		
Middle Clouds		6 km
Altostratus	(Anvil head)	(about 20,000 ft)
Altostratus		
Low Clouds		3 km
Clouds with vertical development		(about 10,000 ft)
Cumulonimbus		
Stratus	Cumulus of fair weather	1.5 km
Nimbostratus	Stratocumulus	(about 5,000 ft)
		(Ground) 0

Figure 4 Clouds affect atmospheric heating by absorbing or blocking solar radiation and trapping Earth’s radiation. Cloud cover also helps to reduce daytime temperature and increase nighttime temperature.

Reading Check

Answer Smog forms when pollutants trigger condensation in air that is not fully saturated with water vapor.

Inquiry Lab

Modeling Atmospheric Composition

Question How can you use liquids to model the composition of atmospheric gases?

Possible Materials 100-mL graduated cylinder, beaker, water, vegetable oil, rubbing alcohol, food dye

Estimated Time 20 minutes

Teaching Strategies

- Students should wear safety goggles and clothes aprons.
- Have students use a graduated cylinder to measure 78 mL of water into a beaker. This will represent the percentage of nitrogen in the atmosphere. They can measure 21 mL of vegetable oil to represent oxygen and pour the oil into the flask. 1 mL of an alcohol can be poured into the flask to represent trace gases.
- Food dye can be used to color the water and alcohol.

For additional inquiry activities, see Science Inquiry Lab Manual.

Activity

Modeling Raindrops Give each pair of students a dropper, water, and a long, rectangular, plastic container with a lid. Have students prop the lid in the container so that it forms a steep slope. Tell them to dribble drops of water down the lid making sure that the entire lid is used. Students should observe that the water droplets collide and combine into bigger drops. Explain that this same process occurs in the clouds during the formation of precipitation. **L2 ELL**

Visual-Spatial

Reading Strategy

Synthesize and Summarize Have students write summary paragraphs for each of the following topics: Atmospheric Structure, Atmospheric Heating, and Water in the Atmosphere. Remind students to look for main ideas and supporting points as they read. They then should synthesize the information into their own words.

Differentiated Instruction

Hearing Impaired To help students with hearing impairments, be sure to write important points on the board when lecturing. Also, use hand gestures to explain key concepts. For example, outline the process of cloud formation on the board. As you discuss rising air, use your hands to show how the air expands. **L2 ELL**

Plants Transpiration is affected mostly by the relative humidity of the atmosphere. The greater the relative humidity of the air is, the lesser the rate of transpiration in plants.

Post Reading

Graphic Organizer Provide slips of paper with the terms *atmosphere*, *troposphere*, *temperature inversion*, *stratosphere*, *greenhouse effect*. Students should write the relationships between words as they create a graphic organizer. For example, between *atmosphere* and *troposphere* students might write *layer*.

3 Assess

DAILY INTERVENTION

Check for Understanding

Visual-Spatial Have students sketch the water cycle. Sketches should show evaporation, condensation, and precipitation. **L2**

ELL

Reteach

Earth's Atmosphere On the board, outline the steps in the formation of Earth's atmosphere, including original atmosphere; hydrogen and helium; gases from volcanic eruptions; photosynthesis and accumulation of oxygen; and formation of ozone layer. **L1 ELL**

Figure 5 Earth's continual cycling of water strongly affects weather and climate.

Plants Transpiration is the loss of water through pores in the leaves of plants. More than 90 percent of the water that enters a plant returns to the atmosphere through the process of transpiration. Research how humidity and air temperature affect transpiration rates in plants. Share your findings with your class.

Global Water Cycle

Precipitation, runoff, storage, and evaporation make up the global water cycle, shown in **Figure 5**. Plants are an important part of the water cycle. They affect absorption and runoff and return water to the air by evaporation from their surfaces.

People affect the water cycle in many ways. They use groundwater for irrigation or pump it from wells. They replace forests with agricultural fields and pave land to build cities. Many of these changes have reduced water quality and resources. Conserving water resources requires careful planning.

section 1 review

Summary

Atmospheric Structure

- The stratosphere and the troposphere are two lower layers of Earth's atmosphere. Most weather takes place in the troposphere.

Atmospheric Heating

- Most solar radiation first heats Earth's surface, which then heats the atmosphere.
- Characteristics of the land surface greatly influence atmospheric heating.

Water in the Atmosphere

- Cloud formation generally requires moist air, rising and cooling, and condensation nuclei.
- Water is cycled through Earth's system by precipitation, runoff, storage, and evaporation.

Self Check

1. **Describe** how temperature of the atmosphere changes with height and explain why.
2. **Explain** the greenhouse effect.
3. **Explain** why small changes in the amount of trace gases are so important in heating Earth's atmosphere.
4. **Identify** what must happen before rain can occur.
5. **Compare and contrast** cumulus and stratus clouds.
6. **Think Critically** How might changes on Earth's surface, such as deforestation, have an effect on weather?

Applying Math

7. **Use Percentages** If the southern hemisphere contains 10 percent land and the northern hemisphere contains roughly 40 percent land, what percent of Earth is land?

section 1 review

1. In the stratosphere, temperature increases with height; in the troposphere it decreases with height.
2. Water vapor, carbon dioxide, and trace gases transmit solar radiation to the surface, but absorb the Earth's infrared radiation, preventing it from escaping into space.
3. Trace gases are stronger absorbers than nitrogen and oxygen and heat the atmosphere more.
4. First, the air must be completely saturated. Then the water vapor must condense into droplets, usually around condensation nuclei.
5. Both types of clouds form as water vapor condenses. Stratus clouds are layered, form slowly, and produce drizzle or slow rain. Cumulus clouds are large and puffy, form rapidly, and usually produce showers.
6. Changes on Earth's surface, such as deforestation, alter the absorption of solar radiation. This leads to uneven heating of Earth's atmosphere that causes differences in air pressure, wind, and other weather conditions. Also, deforestation alters concentrations of atmospheric CO₂ and water vapor, which are trace gases.
7. 25 percent

Visualizing a Temperature Inversion

Normally temperature decreases with increasing altitude in the troposphere. Sometimes near the ground, a temperature inversion occurs and air becomes very stable and resists rising. This can result in fog or smog in cities. Will a liquid behave in the same manner as the atmosphere?

Real-World Problem

How can you visualize what happens during a temperature inversion?

Goals

- **Make a model** that demonstrates a temperature inversion.
- **Apply** what you observe to explain what happens in the atmosphere during a temperature inversion.

Materials

10-mL beaker containing 2–3 mL water
 500-mL beaker containing 250 mL water
 1,000-mL beaker containing 750 mL water
 food coloring
 ladle
 long-stem dropper
 thermal mitt
 freezer
 hot plate

Safety Precautions

Procedure

1. Chill 750 mL of water in a 1,000-mL beaker to near freezing.

2. Add one to two drops of food coloring to the water in the 10-mL beaker and let it stand at room temperature.
3. Heat 250 mL of water in the 500-mL beaker to near boiling.
4. Hold the ladle at the surface of the chilled water. Very slowly pour all the heated water into the ladle and allow it to slowly flow out of the ladle onto the surface of the chilled water. You should have a bottom layer of cold water and a top layer of hot water.
5. Use the long-stem dropper to inject a few drops of the colored water from step 2 into the cold water in the 10-mL beaker.

Conclude and Apply

1. **Describe** what happened to the colored water.
2. **Explain** why this happened in terms of the temperatures of the water layers.
3. **Infer** how this is related to temperature inversions in the atmosphere.

Communicating Your Data

Write a brief paragraph describing your experiment and your observations. Include a labeled diagram showing the temperature layers and explain what happened to the colored water.

LAB 523

Communicating Your Data

Ask students to use their paragraphs and diagrams to explain temperature inversions to friends and family members.

Real-World Problem

Purpose Students use a liquid to model a temperature inversion in the atmosphere.

Process Skills make models, observe, predict

Time required about 30 minutes or one class period

Procedure

Safety Precautions Caution students to handle the hot water carefully and not to touch the hot plate.

Teaching Strategies

- Chill water before class and divide it among student groups.
- Demonstrate the proper way to pour the hot water and suggest that one student hold the ladle while another pours.

Conclude and Apply

1. The colored water remained trapped between the layers.
2. The room-temperature colored water floated on the cold water because it was less dense and sank beneath the hot water because it was denser.
3. The cold water at the bottom is similar to the cooler air near the ground during a temperature inversion. The colored water models a stagnant air mass that might hold pollutants.

Assessment

Process Ask students to predict the effects of rapidly pouring more cold water into the container. How might this relate to atmospheric conditions? [L2]

Weather Ask students if they watch the weather forecasts on television. Ask them how accurate they think these forecasts are and why they are sometimes incorrect. Ask them how weather forecasts affect their lives. L2

Structural Word Analysis

Have students break new vocabulary words into word parts. Ask them to predict meaning by examining the word parts. For example, *jet* refers to a high-speed fluid stream. *Stream* implies a steady current. From this, students could determine that *jet stream* is a high-speed wind current.

Reading Guide

What You'll Learn

- **Explain** what causes Earth's major wind and pressure systems.
- **Describe** typical daily weather patterns around lows and fronts.
- **Describe** the most important storm systems and forms of severe weather.

Why It's Important

Weather affects the health, life, and livelihood of everyone on Earth.

Review Vocabulary

gradient: the rate of change of a quantity with distance

New Vocabulary

- westerlies
- jet stream
- subtropical high
- weather front

Atmospheric Pressure

Although you usually are unaware of it, the atmosphere presses down on you with a pressure equivalent to one kilogram per square centimeter. This pressure is caused by gas molecules moving and colliding with each other and any surfaces they touch. Because the number of air molecules decreases as altitude increases, pressure always decreases with altitude. This is why air is said to be thinner in the upper atmosphere. The number of air molecules, including oxygen, decreases in proportion to pressure. This is why jet aircraft cabins are pressurized and why climbers can get mountain sickness at altitudes over 3,000 m.

Figure 6 In the northern hemisphere, four major pressure belts produce three major wind belts.

Infer How does pressure affect wind direction?

Global Winds and Pressure Systems Weather patterns result from complex global patterns of wind and pressure.

Figure 6 shows a simplified picture of the Earth's major pressure belts that give rise to major wind belts. The most important of these are the **westerlies**—winds that blow from the west in the middle latitudes—and the trade winds, which blow from the east, in the tropics.

Two factors produce these global patterns—unequal heating between the equator and poles and the rotation of Earth. Warm air rising near the equator and sinking over the poles creates general north-south wind circulation. Earth's rotation produces an east-west deflection of this general circulation pattern.

Jet Streams Imbedded in these wind systems are fast and powerful **jet streams** that control many weather processes, such as storm development. Most important for the United States is the polar front jet stream, a wind maximum in the westerlies located about 12 km above the surface. Its speeds can exceed 500 km/h. Major storm tracks follow it as it moves north and south with the seasons.

High and Low Pressure Systems

The large-scale weather systems that have the most effect on the United States are the subpolar lows, westerlies, and the subtropical highs. **Subtropical highs** are relatively stable belts of high pressure near latitudes of 30°. In contrast, sub-polar lows and the westerlies tend to meander as smaller cells of high and low pressure develop. The lows generally develop from a disturbance in the polar front jet and move eastward with the jet stream.

Specific patterns of weather are associated with high and low pressure cells because of the way air flows around them. In the northern hemisphere, winds blow counterclockwise around lows and clockwise around highs, as shown in **Figure 7**. In the southern hemisphere, the directions reverse. Lows are associated with rainfall and storms, and highs with calm winds and clear skies.

INTEGRATE **Coriolis Effect** Airflow around low or high pressure areas results from the net forces acting on the air. First, the pressure gradient pulls the air toward low pressure. Then an apparent force, called the Coriolis effect, deflects the air to the right in the northern hemisphere. When these forces are balanced, air flows perpendicular to lines of equal pressure. Near the surface, friction slows air and modifies its direction, turning it slightly toward low-pressure centers and slightly away from high-pressure centers. This causes air to rise in the center of lows and to sink in the center of highs.

Figure 7 At Earth's surface in the northern hemisphere, air moves counterclockwise toward low pressure and clockwise from high pressure.

Infer How does air move when it is high above Earth's surface, above each pressure system?

Visual Learning

Figure 6 Make sure students understand that winds are named for the direction from which they blow. Thus, westerlies blow from the west toward the east; easterlies blow from the east toward the west. Also, point out that the model of global winds is greatly simplified. It does not take into account many factors that affect wind flow, such as land masses. **L2 ELL**

Caption Answer

Figure 7 Above a surface high pressure system is an atmospheric low. In the northern hemisphere, the air moves counterclockwise toward the atmospheric low. It moves clockwise away from an atmospheric high.

Modeling the Coriolis Effect

Procedure

1. Put a large, round piece of cardboard or paper on a turntable surface such as a turntable.
2. Hold a ruler just above the diameter of the cardboard.
3. Ask someone to turn the surface while you draw a line across the turning cardboard with your pen or pencil against the ruler.
4. Repeat step 3 but turn the surface in the opposite direction.

Analysis

1. Compare the outlines drawn on the cardboard.
2. Explain how these outlines represent the Coriolis effect.

2 Teach

Caption Answer

Figure 6 Wind blows from high pressure to low pressure.

Purpose Students will model the Coriolis force.

Materials cardboard, turntable, ruler, marker

Teaching Strategy Advise students to first rotate the turntable in a counterclockwise direction. In doing so, they will model the direction of Earth's rotation from the point of view of an observer over the north pole.

Analysis

1. When the turntable turns counterclockwise, the line curves to the right; when the turntable is turned clockwise, the line curves to the left.
2. The first line represents the Coriolis force in the northern hemisphere; the second represents the Coriolis force in the southern hemisphere.

Assessment

Content Explain that the Coriolis force is an effect caused by Earth's rotation. Ask students the following question: How would air move across Earth's surface if Earth did not rotate? in a straight line

Content Background

The amount of deflection associated with the Coriolis force is affected by latitude and wind speed. The Coriolis effect is nearly nonexistent at the equator. It is strongest near the poles. The effect also increases with wind speed. Thus, a strong wind blowing at a high latitude will exhibit a much greater deflection than a weak wind blowing at a low latitude.

Post Reading

Illustrations Have students make illustrations of the following: global wind patterns, fronts, and wind patterns in a severe storm, such as a thunderstorm or a hurricane. Students should refer to the text and can do research using library resources. Remind students to label all illustrations.

Science Online

Topic: Hurricane Tracking

Visit fl.gpscience.com for Web links to information about hurricanes and hurricane tracking.

Activity Research six hurricanes. Make a table that lists how each was tracked as a tropical depression and then as a hurricane.

Figure 10 Texas, Oklahoma, and Kansas frequently experience tornadoes.

Tornadoes and Hurricanes Two types of violent wind storms that differ greatly in their origins and effects are tornadoes and hurricanes. Tornadoes are intense, short-lived, localized storms in the mid-latitudes. They originate in cumulonimbus clouds under special conditions. Typically, tornadoes that occur in the United States form when dry air from the deserts of Mexico and the southwest overrides warm, moist air from the Gulf of Mexico. This happens frequently in the Great Plains, the lower midwest, and parts of the south, as shown in **Figure 10**. In the south, they often accompany hurricanes.

A twisting, funnel-shaped tornado cloud can move across land at a speed of around 50 km/h creating a path 150 m wide and 10 km long. Intense, circular winds in the funnel can reach speeds up to 400 km/h. The extreme low pressure at the center can result in more damage than that from the wind.

Hurricanes are tropical storms that cover vast areas and last for days. Those affecting the United States often form as tropical depressions over the warm waters of the southern Atlantic off the coast of Africa. When winds exceed 118 km/h, the storms are called hurricanes. A typical hurricane consists of vast cloud bands that spiral inward toward the clear center, called the eye. Scientists often fly into the eye to study the storm. Western Pacific hurricanes are called typhoons.

section 2 review

Summary

Global Wind and Pressure Systems

- Four major pressure systems produce three major wind systems in each hemisphere.

High and Low Pressure Systems

- Air flows counterclockwise around lows and clockwise around highs in the northern hemisphere.
- Air rises in the center of lows and sinks in the center of highs.

Weather Fronts and Severe Weather

- Air masses interact at weather fronts.
- Warm fronts are associated with stratus-type clouds and cold fronts with cumulus-type clouds.
- Severe weather includes hurricanes, tornadoes, and downbursts.

Self Check

1. **Explain** how Earth's rotation affects winds.
2. **Compare and contrast** tornadoes and hurricanes.
3. **Infer** the wind directions around a high in the southern hemisphere.
4. **Describe** common differences between continental air masses and maritime air masses.
5. **Compare and contrast** warm fronts and cold fronts.
6. **Think Critically** If the polar front jet stream were to move southward over the U.S., what other weather systems are likely to be affected?

Applying Math

7. **Use Percentage** A tornado watch was issued on 25 days during one year in a midwest city. What percent of the year does this represent?

section 2 review

1. In the northern hemisphere, winds are deflected counterclockwise toward low pressure and clockwise away from high pressure.
2. Tornadoes and hurricanes are storms with violent winds. Tornadoes are brief, cover small areas, and occur in the mid-latitudes. Hurricanes are of longer duration, cover large areas, and begin in the tropics.
3. counterclockwise
4. Continental air masses originate over land, are relatively dry, and commonly exhibit extreme temperature variations. Maritime air masses originate over oceans, are relatively moist, and usually exhibit less extreme temperature variations.
5. Both are zones where air masses interact. In warm fronts, cold air gently pushes warm air above it, bringing layered clouds and light or steady rain. In cold fronts, cold air chaotically pushes warm air upward, forming cumulus and cumulonimbus clouds, which can produce brief showers.
6. Because the major storm track follows the polar front jet, it would move southward too.
7. $25/365 = 6.8$ percent

Climate

Climate Characteristics Ask students to name types of climates. Students might mention terms such as mild, rainy, cold, or warm. Ask them what aspects of weather these terms include.

L2

Activate Background Knowledge

Have students preview new vocabulary terms. As a class, ask them to brainstorm ideas related to each term. Guide students toward a deeper understanding of the terms by asking clarifying questions.

Climate and Weather

What is the climate where you live? Traditionally, climate means the long-term average of weather conditions—wind, temperature, precipitation, moisture, and other aspects of weather. Climate also describes the annual variations of these conditions and their extremes.

Averages of data collected monthly over 30 years or longer are used to define climatic normals. These normals do not describe usual weather conditions of an area, but are only averages of conditions measured at one local site. For example, the conditions in a city might vary from what is measured at an airport weather station outside the city.

Climate System Climate is best considered as part of the whole Earth system. This biogeophysical system can be visualized as five spheres that interact to create the environments in which we live, as shown in **Figure 11**. The atmosphere includes the air around us. The **biosphere** is everything organic, including plants, animals, and humans. The hydrosphere is liquid water in oceans, lakes, rivers, soil, and underground. The cryosphere is frozen water in snow, ice, and glaciers. Finally, the lithosphere is the solid Earth, including its soil, rocks, and mantle.

Figure 11 All of the five spheres shown below interact. Each sphere causes changes in, and is changed by, the others.

Use an Analogy

Weather v. Climate To help students distinguish between weather and climate, tell them that weather is like a single test score. That score represents what a student knows at one point in time. Climate is like a final grade. It is the average of many different factors over a longer period of time.

Make a Model

Earth's Spheres Form small groups of students and have them make models showing Earth's five spheres. Students can use plants, water, crushed ice, and sand to represent the biosphere, hydrosphere, cryosphere, and lithosphere, respectively. Have students set up their models in large plastic containers. Then place an electric fan near one of the models. Turn it on and have students observe interactions among the spheres. Ask: What does the fan or drier represent? **atmosphere** What interactions did you observe among Earth's spheres? **Students might note that the "wind" caused the sand to erode. They might see the melting ice cause the water level to rise or that wind caused the plants to wilt. The breeze of the fan might cause waves that erode the sand. Ask students about the consequences of removing one of the spheres. Removing the hydrosphere might affect the biosphere. Removing the cryosphere might affect the hydrosphere. You might extend the activity by having students observe the model over a period of time and note changes among the spheres.** [L2]

ELL Visual-Spatial

Caption Answer

Figure 12 The northern hemisphere is tilted toward the Sun.

Science Online

Topic: World Climates

Visit fl.gpscience.com for Web links to data on mean annual temperature and rainfall of world cities.

Activity Use a world atlas, globe, or large classroom map to find a city corresponding to each of the eight climate divisions shown in Figure 17.

Sphere Interactions Gases, water, soluble materials, energy, and particulates are exchanged among these spheres. Each sphere affects all the other spheres. For example, volcanic eruptions transfer gases and particles from the lithosphere to the atmosphere. The atmosphere provides and regulates the amount of water in the hydrosphere and cryosphere, and provides water, carbon, and oxygen for the biosphere. Through winds, atmosphere causes erosion, creates soil, and absorbs and emits energy from the Sun. When you consider all these complex interactions, you can see why it's better to define climate as the average weather conditions, their variability and causes, and inter-relationships of many individual systems within the global Earth system. One example how such systems are inter-related is illustrated in Figure 12.

What causes climate?

Latitude is the primary factor that determines climate at a given location. The amount of radiation received from the Sun and the prevailing circulation features depend on latitude. Other factors are location near high mountains or on the east or west sides of a continent and distance from major bodies of water.

Causes of Mean Temperature The amount of solar radiation received and surface temperatures vary greatly from the equator to the poles. In the winter, the amount of solar radiation varies, because of the low angle at which it strikes Earth. As a result, temperatures decrease rapidly with increasing latitude. The high reflectance, or albedo, of snow and ice in high latitudes adds to this decrease. In summer, temperature decrease is less pronounced as sunlight strikes at a higher angle and periods of daylight are longer. The temperature patterns over the United States illustrate this, as shown in Figure 12. The strong temperature gradients in winter and spring help to create storms and severe weather.

Figure 12 Lines drawn on a weather map that connect points of equal temperature are called isotherms.

Infer Why are warmer temperatures shifted northward in July?

Curriculum Connection

Geography Remind students that latitude is the distance in degrees north or south of the equator. Longitude is the distance in degrees east or west of the prime meridian. Have students use a world map or globe to locate the equator, the prime meridian, and the latitude and longitude of where they live. [L1] ELL

Teacher FYI

Red Tides Scientists have found a connection between giant dust clouds from Africa that deposit dust containing high levels of iron in waters near Florida and toxic algae. Increased iron levels encourage growth of algae in the water that kills large numbers of sea animals—the red tide. This shows the interactions of four of the five spheres.

Figure 13

The Namib desert illustrates the interconnectedness of climate, geology, plants, and animals. It is created by high pressure, wind, and cold ocean currents along the west coast of southern Africa.

The desert is constantly reshaped by the wind. Transverse dunes show that the wind blows in one preferred direction. Dunes also begin when isolated plants trap sand. However, most deserts are not covered with sand dunes—they are made of stony pavement left behind when wind strips the desert surface. Winds and water remove the finer surface materials, leaving stones behind. This process is called deflation.

Dense coastal fog forms when the air above cold ocean currents interacts with moist desert air. Although deserts may appear to be dry, the air above ground contains lots of moisture. Condensation from fog produces fog-water, which drips into desert pavement and dissolves rocks, forming new sediment. It also forms small pools below the stony surface, which support plant growth. Desert plants have special adaptations such as a dense, compact form and thick, waxy coats. This helps protect them from both heat and animals.

The Welwitschia plant grows in this barren land by absorbing fog-water through its elongated leaves. It is a relic of millions of years ago and is found only in the Namib.

Transverse dunes form perpendicular to the wind.

Star-shaped dunes form when winds are variable.

Stone pavement is more common in a desert than dunes.

Beetles capture fog-water by basking upside down or forming trenches at the bottom of dunes. They also survive beneath the leaves of Welwitschia plants where temperatures may be 30°C cooler than the surround bare ground.

SECTION 3 Climate **531**

Visualizing Earth's Biogeophysical Systems

Have students examine the pictures and read the captions. Then ask the following questions: Explain why some areas of the Namib appear so different from others. *Wind shapes dunes. Some winds blow exclusively from one direction and produce dunes with crests perpendicular to the wind. Variable winds produce star-shaped dunes.* Explain why so many deserts might consist of stony pavement rather than sand. *Dunes usually start when sand is trapped by isolated vegetation. With no vegetation, sand does not collect, but may be blown thousands of miles. Also, the type of rock present may not be easily eroded by wind.* If coastal fog contains so much moisture, why don't more plants exist along the coast? *Fog condenses only when the temperature drops below its dew point. This happens only in the cool night or morning and in shaded crevices, so only plants that can absorb moisture rapidly and retain it can survive.*

Activity

Ask students to research mechanisms that help plants and animals survive under harsh environmental conditions. Ask each student to find one example and present it to the class along with a photo or drawing. The pictures can then be grouped on posters, according to the conditions—for example, aridity, heat, or cold. **L2** **IS** Visual-Spatial

Differentiated Instruction

Challenge Have students research a desert in the southwestern United States and make a presentation to the class. The presentation should include how the desert formed, conditions, and the survival mechanisms of plants and animals. During the presentation they might ask students to compare and contrast aspects of this desert with the Namib. **L2** **IS** Linguistics

Discussion

Factors that Influence Climate After students have read about types of climates, have them summarize the factors that affect the climate of San Francisco. **San Francisco** is located near the coast so it is influenced by ocean currents. The city also lies in the path of the prevailing westerlies. This strengthens the influence of the ocean currents, giving San Francisco a strongly developed maritime climate. [L2]

Teacher FYI

ITCZ Near the equator, the trade winds converge along a shifting boundary known as the Intertropical Convergence Zone (ITCZ). In July, the Sun is more directly over the northern hemisphere. This area receives the maximum amount of radiant energy. In response, the ITCZ moves north. The opposite occurs during January. The sun is more directly over the southern hemisphere, and the ITCZ moves south. This seasonal movement of the ITCZ strongly affects the amount of precipitation received throughout the year by areas located north or south of 30° latitude.

Caption Answer

Figure 14 equal

Ocean and Land Influence Oceans and ocean currents modify the basic climate. Areas with little direct ocean influence are called **continental climates** and have steep temperature gradients. A climate with strong ocean influence is called a **maritime climate**. Maritime climates are milder—summers are cooler, winters are warmer, and daily temperatures vary less. The continental climate of Peoria, Illinois, and the maritime climate of San Francisco, California, illustrate the contrast. Although both are near 40° N latitude, the temperature difference between the warmest and coldest months is about 8° C in San Francisco and 30° C in Peoria. Maritime effects are strong enough to keep winters at arctic Spitsbergen, Norway at 78° N latitude, warmer than in International Falls, Minnesota at 48° N latitude.

Precipitation Wind and pressure patterns determine precipitation. Humid climates are associated with low-pressure areas in the tropics and the middle latitudes. Rainfall is greater near the equator because the trade winds of both hemispheres converge there, increasing the rising motion. Arid climates are common where high pressure prevails, and aridity is particularly intense in the subtropics on the eastern sides of the subtropical highs.

Superimposed upon this general pattern are differences related to location on a continent, as shown for North America in **Figure 14**. The west coast lies east of the subtropical high, which brings cold water currents and stable air. This creates the dry climates of California and the southwest. The east coast lies west of the subtropical high, where southerly winds bring warm, unstable air from the Gulf of Mexico that increases precipitation. Air masses can also influence the amount of precipitation an area receives. When continental polar air masses, which originate in the cold, dry arctic regions, move across the Midwestern states in the winter, cold, dry weather results.

Another factor affecting precipitation is the prevailing winds. Because westerlies prevail in the middle latitudes, the maritime influence is stronger on the west coast. This explains why San Francisco has a strongly developed maritime climate, but Boston has a continental climate.

Figure 14 Lines drawn on a map that connect points of equal precipitation are called isohyets or isohyetal lines.

Research What does the prefix *iso-* mean?

532 CHAPTER 17 Weather and Climate

Fun Fact

The world record for the hottest temperature belongs to El Azizia, Libya. In 1922, a temperature of 58°C (136°F) was recorded. The world record for the coldest temperature is held by Vostok, Antarctica. In 1983, a temperature of -89°C (-129°F) was recorded.

Reading Strategy

K-W-L Have students make a four-column table. In the first column, students should list *mean temperature, ocean/land influence, precipitation, mountain and water influence*. In the second column, they should write what they know about each. In the third column, they should list what they want to know. After they read, have students record what they learned in the last column.

Figure 15 The lee rain shadow of the Sierra Nevada and Rocky Mountains accounts for much of the decreased precipitation shown in Figure 14.

Influence of Mountains The Rocky Mountains and the Sierra Nevada also influence the climate of the west. They act as barriers in the wind, blocking weather systems and altering patterns of precipitation. When the wind blows perpendicular to one side of a mountain range, a **lee rain shadow** forms on the opposite side, as shown in **Figure 15**. The Great Plains lie in the lee shadow of the Rocky Mountains and are relatively dry.

Influence of Water Coasts and lakeshores can affect regional climates in several ways. In winter, lake-effect snow often results in regions around the Great Lakes, like those shown in **Figure 16**. As cold, continental air from the north passes over warmer lake water, the air mass gains heat and moisture. When the air mass reaches the colder land to the south or east of a lake, heavy precipitation, in the form of snow, occurs.

Another example of how coasts affect regional climate is a sea breeze. A **sea breeze** (or lake breeze) blows from the water toward the land in the afternoon, when the land is warmer than the water. Warm air rises over the land creating low pressure that allows cool, dense air to blow from the sea toward land. The reverse happens at night when the land is cooler than the water. A land breeze occurs when cool, dense air over land creates high pressure causing the air to blow from the land toward the sea.

Climate Scale Many small-scale variations are superimposed upon the large-scale climate patterns. Some are regional or local and others, termed microclimates, are variations within small distances. For example, cities create a condition called the heat island effect. Building and pavement materials heat more rapidly than bare land. Vehicles and industry produce pollution that retains heat. Air rises over a heat island, pulling in air from the surrounding countryside. On some clear, calm nights, downtown San Francisco can be as much as 8°C warmer than the surrounding rural areas.

Figure 16 People often experience similar weather events near large bodies of water. Cities east of the Great Lakes experience lake-effect snow.

Quick Demo

Lee Rain Shadow

Materials sponge, water, plastic folder, large plastic container

Estimated Time 15 minutes

Procedure Open the plastic folder and turn it upside down within the plastic container, so that the folder forms a model mountain. Dampen the sponge and squeeze it as you move the sponge up the windward side of the “mountain.” Continue to move the sponge, now dry, down the leeward side of the mountain. Ask students what type of climate would be found on the leeward side of the mountain.

dry climate [L3]

Activity

Microclimates Have students take temperature readings in a sunny field on the school grounds and in the shadow of the school building. Have them explain the differences in temperature moisture, and plant growth. **The area in the shadow of the school building is a microclimate. Its temperatures are generally cooler than those in the open field.** The area might be drier if an overhang shields it from rain and might be wetter if near a downspout. Plant growth might vary, depending on available light and moisture. [L2] [ELL]

[L2] [ELL] **Visual-Spatial**

Differentiated Instruction

Learning Disabled Help clarify the connection between vegetation, temperature, and precipitation for students with learning disabilities. Point out that some plants, such as fir trees, can withstand cold temperatures. Other plants, such as cacti, thrive in warm climates. Plants also have different

moisture requirements. When scientists study an area’s climate, they also study the area’s vegetation, among other factors. Vegetation is a visible clue, indicating the temperature and precipitation amounts for an area. [L1] [ELL]

Caption Answer

Figure 17 temperature and moisture

Visual Learning

Figure 17 Have students use the map to describe the characteristics of their area's climate. Answers will vary depending upon students' location. [L2]

Post Reading

Reflection Ask students to respond to the following prompt in their Science Journals: Describe the climate in the region in which you live or in a place you've visited. Using the knowledge gained from reading the text, try to determine influences affecting climate in your area of choice.

Cold Arid	tundra
Cold Dry winter	boreal evergreen forest
Warm Arid	desert
Warm Semi-arid	grassland
Wet winter Dry summer	Mediterranean forest
Wet summer Dry winter	temperate woodland
Warm Wet	subtropical deciduous forest
Warm Wet	tropical deciduous forest

Figure 17 Climate zone influences the types of vegetation that will grow there.

Infer What are two major factors that characterize climate types?

Types of Climates

Geographer Glenn Trewartha and meteorologist Lyle Horn designed a system to classify climates, shown in **Figure 17**. It has three major divisions—cold or boreal, arid and semi-arid, and climates with adequate heat and precipitation. The last includes temperate, subtropical, and tropical climates. These divisions are closely correlated with vegetation.

3 Assess

DAILY INTERVENTION

Check for Understanding

Visual-Spatial Display a globe. Ask students which area receives the most direct sunlight. **equator** Ask students to describe how temperature changes with latitude. **Temperature decreases with distance from the equator.** [L1]

Reteach

Climate Factors Have students work in pairs to quiz one another on the factors that influence climate. [L2] **ELL**

Assessment

Performance Have students work in small groups to design a plan to help reduce the heat-island effect in an urban area. Encourage students to research real solutions used by several different cities. Potential solutions include planting more trees along streets, enlarging parks, and painting rooftops white—most rooftops are dark-colored and absorb heat. [L2] **ELL** **PBL** **Linguistic**

[L2] **ELL** **PBL** **Linguistic**

section 3 review

Summary

Climate and Weather

- Climate is the net result of interactions involving all aspects of the biogeophysical system called Earth.

What causes climate?

- The main causes of climate are the distribution of solar radiation and the location of pressure and wind systems.
- Oceans, land masses, mountains, and large lakes also affect climate.
- Climates are classified on the basis of temperature and moisture availability.
- Prevailing high pressure or the rain shadow of mountains can produce dry climates.

Types of climate

- Climates can be classified into three major divisions.

Self Check

- Explain** why a climatic normal does not tell you exactly what to expect where you live.
- Identify** the five elements of the biogeophysical system called Earth.
- Explain** the association between climate and latitude.
- Compare and contrast** continental and maritime climates.
- Think Critically** Would you expect the daily temperature range to be greater in a maritime climate or a continental climate? Explain.

Applying Math

- Calculate Range** The coolest average summer temperature in the United States is 2°C at Barrow, Alaska, and the warmest is 37°C at Death Valley, California. Calculate the range of average summer temperatures in the United States.

section 3 review

- A climatic normal is an average of conditions over a 30-year period. It does not predict what to expect on any specific day.
- atmosphere, hydrosphere, lithosphere, cryosphere, and biosphere
- Latitude is a major factor that determines climate because it governs the amount of solar radiation received.
- Both are types of climate that depend on location. Maritime climates have a strong ocean influence and usually have a narrow range of temperatures. Continental climates have little or no ocean influence and experience extreme temperature differences between winter and summer.
- The daily temperature range would be greater in a continental climate because the maritime effect would lessen daily differences.
- 35°C

Earth's Changing Climates

Reading Guide

What You'll Learn

- **Explain** how climate changes seasonally.
- **Explain** causes of climate change.
- **Describe** how we influence climate.
- **Explain** El Niño's effect on weather.

Why It's Important

Changing climates affect all life on Earth.

Review Vocabulary

trace: a minute, barely detectable amount present

New Vocabulary

- global warming
- El Niño
- La Niña

Seasonal Changes

Seasonal changes occur as Earth completes a revolution around the Sun. The hemisphere tilted toward the Sun experiences summer while the hemisphere tilted away from the Sun experiences winter. During the summer, a hemisphere receives more intense solar radiation and temperatures rise. During winter, the intensity and amount of solar radiation decreases and temperatures drop. Seasonal changes are magnified in the mid-latitudes by the temperature contrast between land and oceans. The oceans are generally colder than land in the summer, but warmer than land in the winter.

Long-term Changes

Cycles of glaciations, called ice ages, represent long-term climatic change. The peak of the last ice age was 18,000–22,000 years ago when global was about 6°C cooler than present. Glaciers covered much of the middle and high latitudes, as shown in **Figure 18A**. Deserts expanded in the tropics and rainforests all but disappeared.

However, by 5,000 years ago, most of the glacial ice had melted, rainforests returned, and grasslands spread into low latitude deserts. World climate reached its current pattern only about 3,000 years ago, but even since then, large variations have occurred. In the Medieval period, parts of the northern hemisphere were warm and much of the North Atlantic was free of ice, enabling the Vikings to sail to Greenland and establish colonies. A few centuries later, a cooler period called the Little Ice Age occurred, as shown in **Figure 18B**.

Figure 18 The last glacial maximum was 18,000 years ago when Earth's temperature was 6°C cooler than present.

Seasons

Materials unshaded lamp, globe

Procedure Place a lamp on a desk in front of the classroom and turn it on. Tilt a globe toward a wall, then circle the lamp, spinning the globe but keeping it tilted toward the wall. Students should observe that different areas of the globe directly face the Sun during Earth's revolution. Ask: What season is it in the northern hemisphere when that hemisphere is tilted toward the Sun? **summer** [L2]

ELL **Visual-Spatial**

Discussion

Ask students to explain why it is difficult for scientists to determine which factor is causing a specific climate change. **Climate is the net result of different factors acting on different times scales.** [L3]

Integrate History

Dinosaur Extinction In 1980, Luis Alvarez published his discovery of the rare earth element iridium, found in a thin layer of clay in Italy. Iridium is common in meteoroids, comets, and asteroids. Further studies showed that iridium had been deposited about the time that dinosaurs became extinct.

Caption Answer

Figure 19 Trees absorb CO_2 and release O_2 into the atmosphere.

Visual Learning

Figure 19 Have students trace the path of a carbon atom through the carbon cycle. Have them begin with photosynthesis in a producer. [L2] **ELL** **Visual-Spatial**

Integrate History

Dinosaur Extinction

The impact of a large asteroid 65 million years ago on Mexico's Yucatán peninsula may have caused the extinction of dinosaurs and other species. The dust from such an impact would have caused months of darkness and drastically lowered temperatures. Animals like dinosaurs that needed large supplies of food would have suffered most. Research what evidence scientists have for such an impact and report your findings to your class.

Causes of Climate Change Numerous factors influence climate and act on diverse time scales. Over millions of years, factors such as mountain building and continental movement are important. Over years and decades, ocean currents, temperatures, and snow and ice cover play a big role. Climate is the net result of all factors on all timescales.

Variations in the receipt of solar radiation are important on a scale of hundreds to thousands of years. Changes related to Earth's orbit are the most important factors, producing changes that determine the rhythmic cycles of glaciation. These include changes in the tilt of Earth's axis of rotation, the shape of its orbit, and the timing of the seasons with respect to distance from the Sun. The tilt, for example, is now 23.5° , but has varied between 21.5° and 24.5° . These changes alter the amount and distribution of solar radiation that reaches Earth.

Sunspots similarly affect the amount of radiation received by Earth. During one period from 1645 to 1715 sunspot activity was very low. This period is correlated with long winters and extreme cold temperatures in Western Europe, known as the Little Ice Age. Sunspots are important on historical time scales. Volcanoes also play a role on this scale. They spew out vast amounts of dust that can block sunlight for years. For example, the eruption of Mt. Tambora in Indonesia in 1815 created the cold weather conditions that gave 1816 the name "The Year Without a Summer."

The Human Factor

Human activities, such as the burning of fossil fuels, manufacturing processes, deforestation, draining of wetlands, and intensive agriculture, have influenced Earth's atmosphere significantly. These activities modify the surface heating and the water and carbon cycles. They also increase the atmospheric concentrations of trace gases, dust and air pollution.

Figure 19 When organisms die and decay, some carbon is stored as humus in the soil and some is released back to the atmosphere as carbon dioxide.

Describe how trees affect levels of carbon dioxide and oxygen in the atmosphere.

Differentiated Instruction

Behaviorally Disordered Help keep students with behavioral disorders engage in classroom activities by assigning them small tasks. For example, students can take turns reading the text aloud and summarize the causes of climate change. They can also outline important points on the board as you lecture, or help distribute hand-outs. [L2]

Active Reading

Cause-and-Effect Chart This strategy is used to focus on cause-effect relationships. Have students write *Global Warming* in the center. To the left, write the apparent causes of the topic. On the right, have students record the effects.

The Carbon Cycle The carbon cycle, as shown in **Figure 19**, follows the exchange of carbon among the ocean, land, and atmosphere. Carbon is the basis of all organic matter. The changes in the carbon cycle are particularly important both meteorologically and ecologically. The carbon cycle is affected in two ways by deforestation and loss of vegetation—less carbon dioxide is absorbed from the atmosphere during photosynthesis, and decaying and burning wood adds carbon dioxide to the atmosphere.

Applying Math Calculate

CARBON DIOXIDE (CO₂) CONCENTRATION Concentration of CO₂ in the atmosphere has increased at a constant rate of about 4.2 percent per decade over at least the last 30 years. Assuming this rate remains constant, you can predict its concentration in the future by using the following formula:

$$\text{CO}_2 (\text{year} + 10) = \text{CO}_2 (\text{year}) + \text{CO}_2 (\text{year}) \times \text{rate of CO}_2 \text{ increase}$$

IDENTIFY known values and unknown values

Identify the known values:

The concentration of CO₂ in 2000 was 369 ppm

Rate of CO₂ increase between 1990 and 2000 was 4.2 percent

Identify the unknown value:

What will be the concentration of carbon dioxide in 2010?

Concentration of CO₂ = ? ppm

SOLVE the problem

Substitute the known values into the equation:

Concentration in 2010 = 369 ppm + 369 × 0.042

Concentration in 2010 = 384.5

CHECK your answer

Multiply 369 × .042 and subtract from 384.5 to get the value in 2000.

Practice Problems

1. Use the same method to find carbon dioxide concentration in 2020.
2. Assuming that conservation efforts reduce the rate of carbon dioxide increase to 2.6 percent per decade, predict the concentration in 2010?

For more practice problems, go to page 879 and visit Math Practice at fl.gpscience.com.

Reading Strategy

Dialogue Have students create a written dialogue between themselves and a family member. In the conversation, the student should explain how carbon cycles between the living and nonliving world and the effect of human activities on this cycle.

Teacher FYI

Effects of Burning Fossil Fuels The burning of fossil fuels adds carbon dioxide to the air and removes oxygen. This activity has caused a slight decrease in atmospheric oxygen over the last century. However, oxygen is much more abundant than carbon dioxide in the atmosphere. Currently, scientists are monitoring the oxygen cycle, but they do not foresee any serious consequences to global climate.

Applying Math

Math Standards

National: 1, 2, 9

Florida: MA.E.1.4.2

Answers to Practice Problems

1. 400.7 ppm
2. 378.6 ppm

LAB DEMONSTRATION

Purpose to demonstrate that burning fossil fuels releases carbon dioxide into the air

Materials balloons, tire pump, car, twist ties, straws, funnel, test tubes, water, bromthymol blue, dropper

Preparation Using a funnel, fill one balloon with car exhaust. Fill the second using a tire

pump. Seal both with twist ties.

Procedure Add 10 drops of bromthymol blue, which turns yellow in the presence of carbon dioxide, to each test tube. Drop a straw into each test tube. Test the contents of each balloon by placing its open end over one of the straws and carefully releasing the twist tie.

Expected Outcome The exhaust fumes cause the solution to turn yellow.

Assessment

How might levels of carbon dioxide in the atmosphere be reduced? **By reducing emissions from vehicles**

Teacher FYI

Environmental Solutions The city in Mexico having the most air pollution is the capital, Mexico City. Many of the city's four million vehicles do not contain modern emission controls. In response, the government has provided incentives to industry and private citizens, promoting the manufacture and use of cleaner vehicles. For example, since 1991, new cars are now equipped with emission controls. Residents in urban areas either must equip their vehicles with catalytic converters or be banned from driving one day each week.

Visual Learning

Figure 20 Have students identify trends they observe in the images of the ozone layer. The concentration of ozone has decreased dramatically since 1979. [L2]

Caption Answer

Figure 20 Ozone shields Earth from ultraviolet radiation.

Activity

Deforestation Have students design and carry out experiments to determine how deforestation affects soil erosion. They can compare rates of erosion in two different containers. One container could hold both plants and soil. The second container could hold soil only. [L3]

Fun Fact

Scientists have determined the historical concentrations of atmospheric carbon dioxide by analyzing samples of air that can be accurately dated. These include air bubbles in ice layers and air trapped in hollow buttons on military uniforms and in sealed bottles of vintage wines.

Figure 20 The concentration of ozone over Antarctic has dramatically decreased between 1979 and 2003. Concentrations in the hole are about eighty percent lower than what would be there naturally.

Explain why scientists are concerned about decreasing concentration of ozone in the stratosphere.

Oct. 1979

Oct. 2003

Trace Gases Today's atmosphere contains on average about 380 ppm of carbon dioxide. This is an increase of 66 ppm, or 21 percent, since measurements began in 1957. This level is far greater still than at the beginning of the nineteenth century, when levels were stable at 280 ppm. Human activities have also increased the concentration of other trace gases—methane by more than 100 percent, nitrous oxide by about 10 percent. All of these gases are important in heating the atmosphere.

Global Warming Global warming is an increase in the average global temperature of Earth. Global temperatures have increased over the last century by about 1°C. This may seem small, but the entire global temperature increase since the last ice age is only 6°C. Our understanding of global warming is incomplete, but evidence strongly suggests that the increase in trace gases is an important component.

The Ozone Hole As early as the 1970s, scientists were concerned that synthetic chemical compounds could destroy atmospheric ozone. They worried about exhaust from supersonic aircraft and chlorine and fluorine compounds, such as the CFCs (chlorofluorocarbons) used in refrigeration, aerosol sprays, and other processes. Since ultraviolet radiation breaks down DNA, less protection from solar ultraviolet radiation potentially could affect the quality of life on Earth. In 1985, British scientists found a hole in the ozone layer over Antarctica.

The change in the ozone layer between 1979 and 2003 is shown in **Figure 20**. When study of the air in this hole showed that it was largely man-made, an international agreement was made to limit the use of CFCs. Recent studies indicate that actions taken as a result of the agreement are having an effect on levels of chlorine in the atmosphere, which are decreasing each year.

The Land Surface Humans change the land surface by draining swamps, plowing fields, and building cities. Extensive studies have suggested that these processes might affect local or regional climate, but the issue is still controversial. The climate of cities is different than the climate of the surrounding countryside. Effects on larger scales are not as clear.

One concern is desertification. Desertification is the end product of many types of changes that make once-productive land unusable. Human activities such as overgrazing of livestock, deforestation, and irrigation of crops may contribute to the process of desertification in some areas of the world.

Cultural Diversity

Adapting to Extremes You have seen how plants and animals can adapt to extreme climatic conditions. Humans use ingenuity and available materials to build shelters. Many Inuits build long- and short-term shelters from blocks of snow. Snow is a good insulation against frigid arctic temperatures. Around the Persian Gulf where summer tempera-

tures are a threat, people once cooled their homes naturally using wind towers. These tall structures had openings in all directions and internal, diagonal walls. Breezes were captured, forced downward and channeled through certain rooms that were used in summer.

El Niño and La Niña

El Niño is a climatic event that involves the atmosphere and oceans. Normally, the trade winds blow warm surface water westward toward a low pressure area in the western Pacific. The warm surface water is replaced by cold, nutrient-rich water that is upwelled from below the surface. When the tradewinds weaken, surface pressure patterns break down and the flow of warm water is reversed. Nutrient-rich cold water is no longer upwelled and warm, nutrient-poor water remains at the surface.

Fewer fish and other marine life can be supported by the nutrient-poor water. Rainfall in the western Pacific decreases, where as heavy rain and flooding can occur on the normally dry coast of Peru. El Niño can dramatically alter global weather patterns. For example, a strong El Niño can lead to flooding and mudslides in California, as shown in **Figure 21**, and droughts in India, Australia, and parts of Africa.

The opposite of El Niño is **La Niña**, which occurs when tradewinds in the Pacific are unusually strong and equatorial oceanic surface temperatures are colder than normal. La Niña can cause drought in the southern United States and excess rainfall in the northwest.

Figure 21 Parts of the Pacific Coast Highway in California have been disrupted by erosion and mudslides caused by El Niño.

Post Reading

Debate and Discuss Have students research the following topics in preparation for a class discussion/debate: causes of global warming, human influence on climate, and causes of the ozone hole. Encourage them to make a case that argues for specific causes and effects.

3 Assess

DAILY INTERVENTION

Check for Understanding

Linguistic Ask students to describe the connection between the greenhouse effect and global warming. *The greenhouse effect is a natural process wherein certain gases trap heat from the Sun. Global warming is a rise in Earth's overall surface temperature possibly caused by an increase in greenhouse gases.* [L2]

Reteach

Climate Change Draw an oval on the board. Inside the oval write *Climate Change*. Under this oval, draw two more ovals. In the first oval, write *Caused by Natural Processes*. In the second oval, write *Caused by Human Activities*. Use lines to connect the second row of ovals to the center oval. Draw a third row of ovals, connected to the second row. With student input, fill in the ovals with examples of different types of climate change. [L1] **ELL** **Visual-Spatial**

section 4 review

Summary

Seasonal Changes

- The tilt of Earth's axis changes the amount of solar radiation received by the northern and southern hemispheres throughout the year, causing the seasons.

Long-term Climate Changes

- Cycles of glaciation occur on the scale of tens of thousands of years.
- Sunspots and volcanoes influence climate on shorter timescales.

The Human Factor

- Human activities have increased the concentration of trace gases and decreased stratospheric ozone.

El Niño and La Niña

- El Niño is a warming of the Pacific Ocean with worldwide effects. La Niña is the opposite of El Niño.

Self Check

1. **Identify** ways that humans may be affecting climate.
2. **Explain** why the contrast between land and water changes with the seasons.
3. **Explain** why it is difficult to identify any single cause of an observed climate change.
4. **Think Critically** What can be done to stop global warming? What can you do to help?

Applying Math

5. **Use Percentages** The eruption of Mount Pinatubo in 1991 put large amounts of dust into the atmosphere. Scientists say this decreased the average global temperature about 0.8 percent during the next year. How would this affect an area with an average temperature of 25°C before the eruption?
6. **Calculate** Areas of the southeastern United States may receive 15 percent of their rain during hurricanes. If average rainfall for this area ranges from 100–200 cm, how much of this might be from hurricanes?

section 4 review

1. Answers include burning fossil fuels, deforestation, paving land, draining swamps, and releasing chemicals that damage the ozone layer.
2. Water absorbs heat slowly but retains heat longer than land. Oceans are generally warmer than land in winter, but cooler in summer.
3. Because climate depends on many factors that operate on different time scales, it is hard to determine which is most important.
4. Answers might include reduce emissions of trace gases, conserve electricity, enact stronger antipollution laws, plant more forests, and develop alternate energy sources.
5. lower average temperature by 0.2°C
6. 15–30 cm

MA.A.1.4.4, M.A.B.1.4.2

Assessment

Oral Tell students that scientists disagree on the causes and effects of global warming. Have students conduct further research on the topic and then debate what the U.S. government should be doing about global warming. [L3] **LS** **Visual-Spatial**

► Real-World Problem

Purpose Students will identify a microclimate and investigate how conditions there differ from the surroundings and determine how this affects life forms or other factors.

Process Skills observe, measure, form and test hypotheses, make a graph, evaluate, infer, predict

Time Required 10-15 minutes a day for one or two weeks

Materials thermometer, rain gauge, meter stick or metric ruler, magnifying glass, camera

Alternate Materials small plastic cups, graduated cylinder

► Form a Hypothesis

Possible Hypotheses

Encourage students to look for small areas that appear different either in plant growth or presence of snow, ice, or water.

After students have identified a possible microclimate, have them select one variable to study. Moisture enhances plant growth, so areas with more precipitation might have more vegetation. Sunlight also encourages plant growth, but some plants require less light than others, so vegetation may vary in size and variety.

Temperature may be a factor also. Sheltered areas protect against freezing temperatures and winds. Shade from buildings affects temperature, and this can cause snow to last longer or have positive and negative effects on life forms. Air temperature at ground level differs from that at higher elevations.

Investigating Microclimate

► Real World Problem

While we can talk about global climate or regional climate, we also can discuss climate on the scale of a few meters. We call climate at this scale a microclimate. For example, because cold, heavy air drains downhill, valley fog sometimes forms in moist, low-lying areas. Along the California coast, coastal fog collects on the needles of redwood trees, drips to the ground, and is absorbed by the tree's shallow root system. This microclimate helps the coastal redwoods survive, nestled in the fog belt along the California coast. In this lab, you will investigate local differences in microclimate.

► Form a Hypothesis

Choose an aspect of climate, such as precipitation, light, or temperature. Form a hypothesis to explain how this aspect influences local environments. Predict how these factors will vary in response to differences in your microclimate variable.

Goals

■ **Investigate** how environmental variables respond to various microclimates.

Possible Materials

directional compass
thermometer
rain gauge
meter stick
small plastic cups
*graduated cylinder
*Alternate materials

Safety Precautions

► Test Your Hypothesis

Possible Procedure Encourage students to take measurements at various distances to define the boundaries of their microclimate. Measure conditions over several days at about five sites.

Teaching Strategy

- Help students choose variables appropriate for the season.
- Make sure that the variable is measurable with the tools available.
- Help students choose appropriate sites and decide when and where to make measurements.

Using Scientific Methods

Test Your Hypothesis

Make a Plan

1. Decide what microclimate factor you will investigate, and what environmental factor you will monitor for effects.
2. How will you measure the selected microclimate variable? What equipment will you need? How often will you make measurements?
3. Choose sites for making measurements. Will these sites vary in microclimate? Is the environmental variable you chose present in these places?
4. Decide how you will measure your environmental variable. What equipment will you need? How often will you make measurements? Should the microclimate measurement happen at the same time?
5. Prepare a data table to record your measurements. Will you record the time of the measurements? Should you record the weather at the time of measurements?
6. Before you begin, list the steps of your procedure. Include all materials needed for each step. Does your procedure give you the data necessary to test your hypothesis?

Follow Your Plan

1. Be sure that your teacher approves your plan before you start.
2. Carry out your experiment as planned. Be sure to record all data in the appropriate places. Follow all appropriate safety precautions.
3. Record all observations and data in your Science Journal.

Analyze Your Data

1. **Make a graph** of your data. Put the microclimate variable on the y-axis, and the environmental variable on the x-axis.
2. **Discuss** any trends you see in the data based on your graph.
3. **Infer** any effects that the weather had on microclimate variables. How did this affect your environmental variable?

Conclude and Apply

1. **Discuss** your predicted environmental response to microclimate. Did your results support your hypothesis?
2. **Predict** how changes in global climate would affect the microclimate and response variables that you studied.

Communicating Your Data

Compare your results with the data of other students who measured the same microclimate variable. Present the combined data to the class. **For more help, refer to the Science Skills Handbook.**

LAB 541

Alternative Inquiry Lab

A Controlled Microclimate To extend this lab, have students confirm their observations and conclusions in a controlled system. For example, they might compare growth of two or three plants. Be sure that they modify only one selected variable, such as moisture, light, or temperature while keeping other variables constant. **L3**

Communicating Your Data

Help students to present their results clearly, using drawings and graphs where possible, so that they can explain them to students who studied different microclimates.

Troubleshooting If no changes are observed in the first few days, encourage students to modify their plans and choose a different area or different variables.

Expected Outcome Varying amounts of shade, warmth, and precipitation will have measurable impacts on snow cover, plant growth, and evaporation rates at different sites.

Analyze Your Data

Answers to questions will vary. Accept all reasonable answers.

Conclude and Apply

Conclusions will vary. Be sure that the results are clearly expressed using diagrams and graphs where possible.

Assessment

Content Have students find other sites similar to those they investigated. Ask them to predict the microclimate in these sites based on their original observations. Use **Performance Assessment in the Science Classroom**, p. 89. **L2**

Understanding Literature

The dust bowl was a tragic period for southern plains states in the 1930s. Ask students what other events took place during the 1930s. Possible answers: the Great Depression, Roosevelt's New Deal, and the rise of Nazi Germany

Respond to the Reading

1. It buries them in dust, damages leaves, stalks, and roots, and blocks essential sunlight.
2. Dust storms have a number of causes, including over-farming and grazing, erosion, removing trees, and drought.
3. **Linking Science and Reading** The effects of different types of severe weather can be similar. Crops are damaged, trees and homes are damaged or destroyed, and lives are disrupted.

The Grapes of Wrath

by John Steinbeck

In *The Grapes of Wrath*, Steinbeck tells the story of the fictional Joad family, who lived in Oklahoma in the 1930s. Like thousands of families living in the drought-stricken dust bowl of the central United States, the

Joads were tenant farmers who lost their farm. Such families piled their belongings into rickety trucks and migrated to California seeking work as fruit pickers.

Although the drought alone caused much hardship, it was gigantic dust storms that finally destroyed their crops. Steinbeck describes such a storm in the following words:

"The wind grew stronger, whisked under stones, carried up straws and old leaves, and even little clods, marking its course as it sailed across the fields. The air and the sky darkened and through them the sun shone redly, and there was a raw sting in the air. During a night the wind raced faster over the land, dug cunningly among the rootlets of the corn, and the corn fought the wind with its weakened leaves until the roots were freed by the prying wind and then each stalk settled wearily sideways toward the earth and pointed the direction of the wind."

When the storm finally ended, the buildings, fences, and trees were blanketed with thick layers of dust—a grim reminder of how the Joads' lives had been changed forever.

Understanding Literature

Historical Novels Authors often use historical events as inspiration. When a piece of fiction combines historical events or characters with fictional plot and dialogue, it becomes a historical novel. Well-written historical fiction can aid the reader in understanding how people actually experienced an important time in history.

Respond to the Reading

1. How does the dust storm affect the crops?
2. What might cause such a dust storm?
3. **Linking Science and Reading** Write a paragraph describing the effects of a hurricane or tornado.

Dust Storms

With no moisture to bring rain, the wind picks up fine soil particles that often remain suspended in air. This irritates eyes and makes breathing difficult. The suspended dust also produces sunset colors. The particle content of the air is high enough to filter out all the blue light. What remains are the longer wavelengths of yellow, orange, and red.

The dust bowl resulted from interactions between natural elements, such as climate, plants, and soil, and human elements, such as farming practices and economics. When the dust bowl occurred, vegetation was already sparse. This reduced friction and allowed the wind to gain speed. With no moisture to bind soil particles together, the soil eroded. Dust from these storms was carried up to 3,000 km away from its original source. The dust storms were a type of squall that sometimes bring rain to these semi-arid plains.

Resources for Teachers and Students

Out of the Dust, by Karen Hesse, Scholastic Press, 1999.

Survival in the Storm, The Dust Bowl Diary of Grace Edwards, by Katelan Janke, Scholastic Press, 2002.

Reviewing Main Ideas

Section 1 Earth's Atmosphere

1. Earth's atmosphere is 78 percent nitrogen, 21 percent oxygen, one percent argon, and includes small amounts of trace gases.
2. The stratosphere is the upper layer of the atmosphere where temperature always increases with height. The troposphere is the lower layer where most weather occurs.
3. The troposphere is heated primarily by Earth's surface after it absorbs radiation from the Sun.
4. Land absorbs and emits heat efficiently, but water resists temperature change.
5. Clouds form when warm air carrying water vapor rises until it is cool enough to condense.

Section 2 Weather

1. Major pressure belts and wind belts are caused by unequal heating between the equator and the poles and modifications resulting from Earth's rotation.
2. Specific weather patterns are associated with high and low pressure cells.
3. Air masses are large blocks of air with similar properties of moisture and temperature throughout. They interact in zones called weather fronts.
4. Severe weather includes thunderstorms, downbursts, tornadoes, and hurricanes.

Section 3 Climate

1. Climate refers to the mean weather conditions and their annual variations in an area.
2. Climate is part of an Earth system that includes the atmosphere, biosphere, hydrosphere, cryosphere, and lithosphere.
3. Latitude is the most important factor in determining climate.
4. Continents, mountains, and oceans influence climate on a large scale, and small-scale variations are termed microclimates.

Section 4 Earth's Changing Climates

1. Long-term changes include cycles of glaciation. Causes of climate change include changes in Earth's orbit, solar activity, volcanism, and human intervention.
2. Global warming has been documented. The reasons for it are complex and not fully understood.
3. Increased concentrations of trace gases and damage to the ozone layer are probably caused by human activities.
4. El Niño and La Niña affect ocean currents and coastal winds, causing serious droughts and flooding in some areas.

FOLDABLES Use the Foldable that you made at the beginning of this chapter to review what you have learned about weather and climate.

Reviewing Main Ideas

Summary statements can be used by students to review the major concepts of the chapter.

Assessment

FOLDABLES

Have students use their Foldables to review weather and climate.

Using Vocabulary

1. weather fronts
2. maritime climate
3. latent heat
4. troposphere
5. El Niño/La Niña
6. westerlies
7. jet streams
8. lee rain shadow
9. temperature inversion
10. greenhouse effect

Checking Concepts

- | | |
|-------|-------|
| 11. A | 15. B |
| 12. A | 16. A |
| 13. C | 17. D |
| 14. C | 18. C |

Interpreting Graphics

19. Accept reasonable diagrams showing subpolar lows and subtropical highs with westerlies in between the lows and highs. Trade winds blow from northeast in the northern hemisphere and southeast in the southern hemisphere.
20. Continental climates have little or no ocean influence and experience extreme temperature differences between winter and summer. Maritime climates have a strong ocean influence and usually have a narrow range of temperatures.
21. Cities at latitudes 41 and 45 have maritime climates; that at 72 and 40 have continental climates.

Thinking Critically

22. The continental U.S. has extreme temperatures of cold and warm air masses and the availability of moisture from tropical oceans.
23. Because ozone filters out harmful ultraviolet radiation, loss of ozone exposes us to this danger.

SC.D.1.4.1, SC.D.1.4.3, SC.D.1.4.4, SC.D.2.4.1

Using Vocabulary

biosphere p.529	maritime climate p.532
continental climate p.532	sea breeze p.533
El Niño p.539	subtropical high p.53
global warming p.538	temperature inversion p.519
greenhouse effect p.520	troposphere p.519
jet stream p.525	weather front p.524
La Niña p.539	westerlies p.524
latent heat p.520	
lee rain shadow p.533	

Match the correct vocabulary word(s) with each definition given below.

1. area of interaction between air masses
2. climate with a strong ocean influence
3. energy used to evaporate water
4. layer of the atmosphere where most weather occurs
5. global weather event(s) that involve oceans and the atmosphere
6. most important of three major wind belts
7. fast, powerful air current that affects many weather processes
8. area of reduced precipitation on one side of a mountain range
9. a region of very stable air that resists rising needed to form clouds and disperse pollution
10. warming of the atmosphere involving heat absorption by trace gases

Checking Concepts

Choose the word or phrase that best answers the question.

11. Which has great ranges in temperature and little ocean influence?
A) continental climate
B) El Niño
C) La Niña
D) maritime climate

12. Which is the percent of solar radiation reflected from the surface?
A) albedo
B) Coriolis effect
C) greenhouse effect
D) urban heat island

13. Which is the most important factor in determining climate at a given location?
A) altitude
B) continents
C) latitude
D) mountains

Use the illustration below to answer question 14.

14. Which influence on regional climate is shown above?
A) continental location
B) lake effect
C) lee rain shadow
D) maritime location
15. Which triggers droplet formation in clouds?
A) evaporation
B) dust
C) ozone
D) thermals
16. What type of weather is most closely associated with a warm front?
A) drizzle or steady rain
B) downbursts or windshear
C) hurricanes or tornadoes
D) thunderstorms
17. Which is a trace gas?
A) argon
B) nitrogen
C) oxygen
D) ozone
18. Which surface reflects solar radiation the most?
A) bare soil
B) forest
C) snow fields
D) ocean

Interpreting Graphics

19. **Illustrate** Earth's major pressure belts and wind belts, with labels showing the westerlies and the trade winds.
20. **Make a table** comparing characteristics of continental and maritime climates.

Use the data in the following table to answer question 21.

City Temperatures

Cities at Degrees N Latitude	Average July Temperature (°C)	Average January Temperature (°C)
72	20	−45
41	21	9
45	29	−2
40	31	−10

21. **Identify** Based on the data in the table above, identify the latitudes of the cities that have maritime and continental climates.

Thinking Critically

22. **Explain** why the continental United States is prone to severe weather, such as tornadoes and hurricanes.
23. **Infer** why scientists are so concerned about finding a hole in the ozone layer over Antarctica.
24. **Form a hypothesis** about how we might determine whether human activities have played a role in global warming.
25. **Identify** some ways that plants and animals might adapt to changing climate patterns.
Hint: Think of how organisms adapt to extreme conditions.

Use the illustration below to answer question 26.

26. **Explain** why a sea breeze blows toward the land in the afternoon, and a land breeze blows toward the water in the evening.
27. **Infer** how global warming might increase the frequency of severe weather, such as hurricanes.
28. **Describe** the carbon cycle and explain how human activities might interfere with it.
29. **Explain** how water droplets form in clouds and the conditions needed to make them fall as some form of precipitation.
30. **Identify** some of the ways that human activities have interfered with the water cycle and describe some results of these activities.
31. **Explain** how El Niño affects global weather patterns.

Applying Math

32. **Convert Units** The high temperature of a summer day in the United States might be 81°F. What would this temperature be in France where they use Celsius temperatures? *Hint: Use the formula $^{\circ}\text{C} = (^{\circ}\text{F} - 32) \times 5/9$.*
33. **Compare Ratios** City A had 175 cloudy days in 2004. In 2004, 56 percent of city B's days were cloudy. Which city had more cloudy days? Show the calculations you did to find your answer.

Thinking Critically

24. Hypotheses may involve correlating human activities as global temperature increases, for example, increases in irrigation, industrialization, and grazing animals or decreases in forest cover caused by deforestation
25. Students may mention that plants adapt to dry conditions by having small leaves or waxy coatings on their leaves. Also, plants and animals may become dormant during dry periods and begin growth only when moisture is available.
26. Cooler, denser air over water blows toward land during the day pushing up warmer, less dense air. A land breeze occurs during the evening when cooler, denser air over land flows toward warmer, less dense air over water.
27. Because hurricanes arise over warm tropical waters, global warming would make hurricanes more likely over wider areas.
28. Carbon is exchanged among three major areas, the ocean, land, and atmosphere. The major ways humans interfere with it are by deforestation and burning fossil fuels.
29. Water droplets form when cloud temperature drops to the dew point. Moisture condenses around fine particles called condensation nuclei.
30. Answers should include draining swamps, paving land, irrigation using well water, replacing forests with agricultural fields.
31. Heavy rain and flooding can occur on the normally dry coast of Peru. Rainfall in the western Pacific decreases. A strong El Niño can lead to flooding and mudslides in California and droughts in India, Australia, and parts of Africa.

Applying Math

Math Standards

National: 1,4,9

Florida: MA.B.1.4.2, MA.B.2.4.1

32. 27.2°C

33. City B; $0.56 \times 365 \text{ days} = 204 \text{ days}$

Record your answers on the answer sheet provided by your teacher or on a sheet of paper. The assessed Florida Benchmark appears above the question.

Multiple Choice

1. Which makes up most of Earth's atmosphere?
 - A. carbon dioxide
 - B. carbon monoxide
 - C. nitrogen
 - D. oxygen

Use the figure below to answer question 2.

2. Which is used by photosynthetic organisms to produce almost all of Earth's atmospheric oxygen?
 - A. carbon monoxide
 - B. carbon dioxide
 - C. methane
 - D. nitrogen

SC.D.1.4.4

3. Which accumulated in the stratosphere over millions of years and shielded Earth from ultraviolet rays from the Sun?
 - A. argon
 - B. nitrogen
 - C. oxygen
 - D. ozone

4. Which type of air mass would most likely be moist and warm?
 - A. continental polar
 - B. continental tropical
 - C. maritime polar
 - D. maritime tropical

5. Which is a series of windy gusts formed when a downdraft hits Earth's surface with particularly strong force?
 - A. hail
 - B. squall
 - C. thunderstorm
 - D. tornado

Use the diagram below to answer question 6.

6. Which is caused by absorption of long wavelength radiation by trace gases?
 - A. condensation
 - B. greenhouse effect
 - C. latent heat
 - D. precipitation

Use the table below to answer question 7.

Land Surface	Albedo
Bare soil	25
Snow	90
Desert	50
Dense forest	10

7. Over which surface is the least amount of solar radiation absorbed?

- A. bare soil
- B. dense forest
- C. desert
- D. snow

8. Which are fast, powerful flows of wind imbedded in global wind systems?

- A. jet streams
- B. sea breezes
- C. subtropical highs
- D. westerlies

Gridded Response

9. If the average concentration of carbon dioxide in Earth's atmosphere at the beginning of the nineteenth century was 280 ppm and it presently is 380 ppm, what percentage of today's concentration existed at the beginning of the nineteenth century?

Test-Taking Tip

Review Never leave any answer blank.

Short Response

SC.8.1.4.3

10. Describe the major differences between the conditions that existed 18,000 years ago from the conditions of the present. Include descriptions of the climatic, geological, and biological conditions.

SC.8.2.1.1

11. Explain how the stratospheric ozone layer is formed. Also explain its importance in regard to the quality of life on Earth.

12. What causes uneven patterns of heating on Earth's surface?

SC.8.1.1.1

13. Which factors cause climate?

Extended Response

Use diagram below to answer question 14.

14. **PART A** What are weather fronts?
PART B How do air masses interact at a cold front?

Gridded Response

9. 73.7 %

Short Response

10. Climate was colder 18,000 years ago. Glaciers covered much of the middle and high latitudes and deserts expanded into the tropics. Rainforests were much smaller.
11. Oxygen from photosynthetic organisms accumulates in the atmosphere. Intense solar radiation converts some of it to ozone. Since ultraviolet radiation breaks down DNA, intense ultraviolet radiation from the Sun could be harmful to life on Earth. Stratospheric ozone shields Earth from ultraviolet radiation.
12. Dry land heats more rapidly than water. This, along with the different amounts of radiation that are reflected from different surfaces causes an uneven pattern of surface heating.
13. Latitude on Earth determines the amount of radiation Earth gets from the Sun and sets up prevailing air and water circulation. Other factors include distance from major bodies of water and the location of mountain ranges on a continent.

Extended Response

14. **Part A:** Weather fronts are zones in which air masses interact.
Part B: In a cold front, a cold air mass pushes the warm air mass upward in a random and chaotic fashion forming cumulus clouds. This often produces showers and thunderstorms.

WebQuest *Art of Neon* is a motivating and challenging investigation of the chemistry of noble gases and how they are used in colorful neon signs and glowing sculptures. Students will research how the noble gases are inserted into bent tubing and made to glow. As a culminating activity, students will design a "blueprint" of their own neon sign, its components, colors, shape, size, and use.

By 1860, scientists knew of about 60 elements. However, they had yet to clearly organize their knowledge. A Russian scientist named Dmitri Mendeleev changed that. Mendeleev loved to play solitaire, a type of card game in which playing cards are arranged into patterns according to their properties. One day, Mendeleev decided to make a set of cards on which he wrote the names and properties of the known elements. Then he began to arrange the cards into rows. The result was a table in which certain chemical properties could be seen to occur periodically—that is, to occur in a repeating pattern. In 1869, Mendeleev published his periodic table (seen here in a more advanced version). He left blank spaces in the table where the pattern seemed to call for elements that were not yet known. Over the next several decades, other scientists refined the table, and new elements were added. Modern periodic tables—like the one probably hanging in your classroom—still follow the basic pattern laid out by Mendeleev.

unit projects

Career Working in small groups, have students explore the diverse use of lasers in a variety of careers—medical, military, police, educational, or artistic light and sound shows. Students should investigate how electrical engineers are designing new equipment for each field to help technicians be more precise and efficient. As a class, design a spider map for lasers and compile each group's information into one large informative display.

Technology Have students research the technology and use of core sampling by geologists. Information should include the mechanics of the actual drilling equipment, range of possible drilling depth, reasons a core sample might be useful in a variety of geological areas, and cost of equipment and drilling process. Students may then design a multimedia advertisement, as if selling drilling equipment to research geologists.

Model Ask students to design an entertaining and engaging game that will review concepts presented in this unit, giving them an opportunity to apply their new knowledge. Ideas might include card games, board games, trivia cards, dice, spinners, and game pieces, as well as complete directions, questions and answers, and a colorful intriguing container.

Additional Resources Visit unit projects at fl.gpscience.com for more information, resources, and assessment rubrics.

How Are Playing Cards & the Periodic Table Connected?

- Tape a deck of cards sequentially on poster board. Ask students how all the cards in a row (period) are alike, and how all the cards in a column (family or group) are alike. *They are all of one suit; the same card value is shown.*

- Remind students that Mendeleev left blank spaces in his periodic table where elements seemed to be missing. Randomly remove several cards and ask students to identify the properties of the cards that belong in the empty spaces. Have them justify their answers and relate them to the empty spaces on Mendeleev's periodic table.

Brilliant Sunset

Chapter
18

Who'd ever think sunsets have such rich, vibrant colors? The color of the sunset depends on the way in which particles in the air scatter light. If the air is relatively free of particles, then the sunset will tend to look yellow. If there are a lot of particles in the air, the result will be a sunset of fiery reds and oranges.

What are some components of air?

1. Wh might ar be referred to as matter?
2. Do you think air pollution can affect how we see the sky? Explain.

Key to Teaching Strategies

The following designations will help you decide which activities are appropriate for your students.

- L1** Level 1 activities should be appropriate for students with learning difficulties.
- L2** Level 2 activities should be within the ability range of all students.
- L3** Level 3 activities are designed for above-average students.
- ELL** ELL activities should be within the ability range of English Language Learners.
- COOP LEARN** Cooperative Learning activities are designed for small group work.
- LS** Multiple Learning Styles logos, as described on page 12T, are used throughout to indicate strategies that address different learning styles.
- P** These strategies represent student products that can be placed into a best-work portfolio.
- PBL** Problem-Based Learning activities apply real-world situations to learning.

Science Content Background

Composition of Matter

Pure Substances

Matter can be divided into mixtures and pure substances. Pure substances can be described as either elements or chemical compounds. Mixtures can be either heterogeneous or homogeneous. Homogeneous mixtures are usually called solutions and have a constant composition. Heterogeneous mixtures have regions with visibly different compositions. Homogeneous liquid mixtures tend to be transparent, whereas heterogeneous liquid mixtures are often cloudy and separate on standing.

Elements

At this time there are at least 111 known elements. All the compounds found on Earth are formed when atoms of two or more different elements combine, creating new materials with new properties.

Properties of Matter

Physical Properties

The characteristics, or properties, that are used to describe matter can be classified in several ways. Physical properties are those that can be determined without changing the chemical composition of the

sample, whereas chemical properties are those that do involve a chemical change in the sample. Intensive properties are those that have values that do not depend on the size of the sample. Extensive properties do depend on the size of the sample. Density, the intensive property that relates mass to volume, is an important and useful physical property. Knowing the density of a substance can be very useful, because it is often easier to measure the volume of a liquid than its mass.

Conservation of Mass

The law of conservation of matter states that matter is not created or destroyed but only converted from one form into another. Thus in a chemical reaction, the amount of matter before the reaction is the same as after the reaction. This is equally true for phase changes. Although a material may turn from a solid to a liquid to a gas, the amount of matter is conserved.

IDENTIFYING

Misconceptions

Find Out What Students Think

Students may think that . . .

Matter is not conserved in physical or chemical changes.

Perceptions are often more dominant than logic, and for students it may look as though matter simply vanishes when it turns into an invisible gas. When wood burns in a fire, it is obvious that only ashes remain, but it is not obvious what has happened to the bulk of the wood. For these reasons, students may not recognize the conservation of matter in physical or chemical changes.

Demonstration

Present Figure 1 to students. Tell them that the mass of the jar with everything in it is 500 g. Suppose the magnifying glass is used to light the candle, which then burns in the oxygen-enriched air for about one minute before going out. Ask students to describe any changes that have occurred in the jar. Is the mass of the jar and everything in it now less than, the same as, or greater than 500 g? The mass is still 500 g.

L2 LS Kinesthetic

Promote Understanding

Activity

Prior to class fill small plastic soda bottles two-thirds full of water, cap the bottles, and freeze.

On the day of the activity, provide each group of students with one frozen bottle and a paper towel. Then ask students in each group to

- dry the outside of the bottle and find its mass.
- predict what the mass of the bottle will be when the water melts.
- leave the bottles overnight so that the water inside them melts.

On the next day, have students dry the outside of the bottles and find their masses.

Make a table on the board with columns labeled *Mass of Bottle with Frozen Water* and *Mass of Bottle with Liquid Water* and a row for each group. Ask a member of each group to fill in the data for that group. With the class, analyze the data in the table. Discuss why the masses stayed the same. Help students realize that the bottles were closed so no mass was added to or subtracted from them. **L2 LS Visual-Spatial, Kinesthetic, Interpersonal**

The Art of Mixtures

When painting, an artist can skillfully mix colors to achieve a certain shade, or the artist can show several individual pigments in a single brushstroke. Paint undergoes physical and chemical changes with time that can make the artist's work endure.

Science Journal Describe the physical changes that take place as the paint dries.

550

Theme Connection

Stability and Change Matter can undergo physical and chemical changes. The stability of a substance affects how and when it will change.

About the Photo

Paints Although the solid colors look homogeneous, pigments are in a solvent or water-based solution to form a mixture called a suspension. Larger particles will settle out, while smaller particles remain in suspension and form a colloid. As paint dries, physical changes and chemical reactions occur, making the final properties of paint different from its original state.

Start-Up Activities

Demonstrate the Distillation of Water

Matter is classified according to the different properties that it exhibits. These differences in properties allow drinking water to be obtained from seawater. These properties could be very important to you if you were stranded on a desert island and needed drinking water. Purified water can be obtained through a process called distillation.

1. Place 75 mL of water in a 200-mL beaker and add 20 drops of blue food coloring.
2. Place the beaker on a hot plate.
3. Add ice to an evaporating dish until the dish is half full. Place the evaporating dish on the beaker as shown in the photo.
4. Turn on the hot plate and slowly bring the water and food-coloring solution to a boil.
5. After boiling the solution for five minutes, carefully remove the evaporating dish using heat-resistant gloves. Touch the drops of liquid on the bottom of the dish to a piece of white paper.
6. Observe the liquid on the paper.
7. **Think Critically** In your Science Journal, write a paragraph explaining where the liquid came from. What was in the beaker that is not in the liquid on the paper?

FOLDABLES™ Study Organizer

Classification of Matter Make the following Foldable to ensure that you understand the content by defining the vocabulary terms from this chapter.

- STEP 1** Fold a sheet of paper vertically from side to side. Make the front edge about 1.25 cm shorter than the back edge.

- STEP 2** Turn lengthwise, with the fold on top, and fold into thirds.

- STEP 3** Unfold and cut only the top layer along both folds to make three tabs.

- STEP 4** Label the tabs *Elements*, *Compounds*, and *Mixtures* as shown.

Define As you read the chapter, define each term and list examples of each under the appropriate tab.

Science online

Preview this chapter's content and activities at fl.ck12.org/science

Video Lab available for this Lab.

Purpose Use this Launch Lab to demonstrate for students how water can be distilled and purified.

Preparation Set up a hotplate and acquire ice for each group.

Materials 200-mL beaker, water, food dye, 100-mL graduated cylinder, evaporating dish, ice, tongs, white paper, and a hot-plate for each group

Teaching Strategy To extend this activity, stage a contest to determine who can design an experiment that produces the maximum distillation rate.

Think Critically

Water droplets from the steam rising from the boiling water will condense on the evaporating dish. The water will be colorless. The distillation process will separate the water from the food dye.

Assessment

Content Have each group imagine they are marooned on a tropical island without supplies. Ask them what island materials or materials they are wearing they could use to construct an apparatus for distilling water. The lens of a pair of glasses could magnify sunlight on dried grass to produce a fire. Empty coconut shells could replace beakers and large tropical leaves could replace the evaporating dish.

Figure 1 All the atoms of an element are alike.

Pure Substances

Have you ever seen a photo hanging on a wall that looked just like a real painting? Did you have to touch it to find out? If so, the rough or smooth surface told you whether it was a painting or a photo. Every material has its own properties. The properties of materials can be used to classify them into general categories.

Every material is made of a pure substance or a mixture of substances. A pure **substance** is a type of matter with a fixed composition. A substance can be either an element or a compound. Some substances you might recognize are helium, aluminum, water, and salt.

Elements All substances are built from atoms. If all the atoms in a substance have the same identity, that substance is an **element**. The graphite in your pencil point and the copper coating of most pennies are examples of elements. In graphite, all atoms are carbon atoms, and in a copper sample, all the atoms are copper atoms. The metal substance beneath the copper in a penny is another element—zinc. About 90 elements are found on Earth. More than 20 others have been made in laboratories, but most of these are unstable and exist only for short periods of time. Some elements you might recognize are shown in **Figure 1**. Some less-common elements and their properties are shown in **Figure 2**.

Most of us think of gold as a shiny yellow metal used to make jewelry. However, it is also an element that is used in more unexpected ways, such as in spacecraft parts. On the other hand, some less-common elements, such as americium (am uh REE see um), are used in everyday objects. Some elements and their uses are shown here.

▲ **ALUMINUM** Aluminum is an excellent reflector of heat. Here, an aluminum plastic laminate is used to retain the body heat of a newborn baby.

▲ **TITANIUM** (tie TAY nee um) Parts of the exterior of the Guggenheim Museum in Bilbao, Spain, are made of titanium panels. Strong and lightweight, titanium is also used for body implants.

▲ **LEAD** Because lead has a high density, it is a good barrier to radiation. Dentists drape lead aprons on patients before taking X rays of the patient's teeth to reduce radiation exposure.

▲ **TUNGSTEN** Although tungsten can be combined with steel to form a very durable metal, in its pure form it is soft enough to be stretched to form the filament of a lightbulb. Tungsten has the highest melting point of any metal.

▲ **GOLD** Gold's resistance to corrosion and its ability to reflect infrared radiation make it an excellent coating for space vehicles. The electronic box on the six-wheel Sojourner Rover, above, part of NASA's Pathfinder 1997 mission to Mars, is coated with gold.

◀ **AMERICIUM** Named after America, where it was first produced, americium is a component of this smoke detector. It is a radioactive metal that must be handled with care to avoid contact.

SECTION 1, Composition of Matter 553

Visualizing Elements

Have students examine the pictures and read the captions. Then ask the following questions.

Why is pure tungsten used for the filaments of light bulbs? Because it is durable and stretchable, and has the highest melting point of any metal.

Why is it important to drape the trunk of your body during X rays? To avoid unnecessary radiation exposure to your vital organs.

Can you think of other ways that the reflective properties of aluminum are used? Answers will vary but may include some of the following: cooking, emergency blankets, and signaling mirrors.

Why would the Sojourner Rover need to reflect infrared radiation? To protect the equipment inside the box from excessive infrared radiation. [L2] [IS] Visual-Spatial

Activity

Smoke Detectors Have students research and find out why americium is used in smoke detectors. Have the students report their findings to the class. [L2]

[IS] Linguistic, Intrapersonal

Differentiated Instruction

Challenge Have students find out why titanium is used for body implants and why it is used in aircraft landing gear. The students should report their findings to their class. [L3]

Discussion

Two Liquids Describe for students two liquids. Tell them that both liquids contain only hydrogen and oxygen, and both liquids are transparent and colorless. How can the two liquids have different identities? **They have different combinations of atoms. One liquid is water, H_2O ; the other is hydrogen peroxide, H_2O_2 .** [L2]

Logical-Mathematical

IDENTIFYING

Misconceptions

Definition of Compounds Students may think that elements made from more than one atom, such as Cl_2 , H_2 , S_8 , or P_4 , are compounds. However, compounds must be made from combinations of different elements.

Use an Analogy

Pedal Power In pedal-powered vehicles, the ratio of one frame to one wheel makes a unicycle. One frame to two wheels forms a bicycle. One frame to three wheels produces a tricycle. Similarly, one carbon to one atom of oxygen makes carbon monoxide. One carbon to two oxygen atoms is carbon dioxide. These compounds do not have the same properties.

Reading Check

Answer Compounds contain two or more different elements.

Figure 3 Chlorine gas and sodium metal combine dramatically in the ratio of one to one to form sodium chloride.

Figure 4 The number of mixtures that can be created by combining substances is unlimited.

Compounds When two or more different elements combine, the substance formed is called a compound. A **compound** is a pure substance in which the atoms of two or more elements are combined in a fixed proportion. For example, water is a compound in which two atoms of the element hydrogen combine with one atom of the element oxygen. Chalk contains calcium, carbon, and oxygen in the proportion of one atom each of calcium and carbon to three atoms of oxygen.

Reading Check

How are elements and compounds related?

Can you imagine yourself putting something made from a silvery metal and a greenish-yellow, poisonous gas on your food? You might have shaken some on your food today—table salt is a chemical compound that fits this description. Even though it looks like white crystals and adds flavor to food, its components—sodium and chlorine—are neither white nor salty, as shown in **Figure 3**. Like salt, other compounds usually look different from the elements in them.

Molecules A particle consisting of two or more atoms that are bonded together is called a molecule. Oxygen in the air, as an example, is a diatomic (two-atom) molecule. A molecule is a basic unit of a molecular compound. The simple sugars you eat; the proteins in your body; and the wool and cotton fibers in your clothes all consist of molecules formed from bonded atoms.

Mixtures

Are pizza and a soft drink one of your favorite lunches? If so, you enjoy two foods that are classified as mixtures, but two different kinds of mixtures. A mixture, such as the pizza or soft drink shown in **Figure 4**, is a material made up of two or more substances that can be easily separated by physical means.

Science Journal

Elements and Compounds Ask students to list in their Science Journals all the elements and chemical compounds they can think of without looking them up. Have them look up the chemical symbols for the elements and the chemical formulas for the compounds. Have them write the formulas next to the names of the substances.

[L2] **ELL** **P** **LS** **Linguistic**

Differentiated Instruction

English-Language Learners Provide physical examples of various elements, compounds, and mixtures, and have them labeled to aid the students in developing their vocabulary.

Heterogeneous Mixtures Unlike compounds, mixtures do not always contain the same proportions of the substances that make them up. For example, a pizza chef doesn't measure precisely how much of each topping is sprinkled on a pizza. You easily can see most of the toppings on a pizza. A mixture in which different materials can be distinguished easily is called a **heterogeneous** (he tuh ruh JEE nee us) **mixture**. Granite, concrete, and dry soup mixes are other heterogeneous mixtures you can recognize.

You might be wearing another heterogeneous mixture—clothing made of a permanent-press fabric like the one shown in **Figure 5A**. Such a fabric contains fibers of two materials—polyester and cotton. The amounts of polyester and cotton can vary from one article of clothing to another, as shown by the label. Though you might not be able to distinguish the two fibers just by looking at them, you probably could if you used a microscope, as shown in **Figure 5B**.

Most of the substances you come in contact with every day are heterogeneous mixtures. Some components are easy to see, such as the ingredients in pizza, but others are not. In fact, a component you see can be a mixture itself. For example, the cheese in pizza is also a mixture, but you cannot see the individual components. Cheese contains many compounds, such as milk proteins, butterfat, colorings, and other food additives.

Figure 5 Heterogeneous mixtures can be hard to detect.

A You can't tell at a glance that this fabric is a mixture of cotton and polyester.

B With a microscope, however, the difference between the two fibers is clear; the polyester fiber is perfectly smooth, and the cotton is rough.

Magnification: 600x

Mini LAB

Classifying Materials

Procedure

1. In your *Science Journal*, create a data table with four columns and 11 rows. Label the columns *Elements*, *Compounds*, *Mixtures*, and *Explanation*.
2. Choose ten items in your home and classify each as an element, a compound, or a mixture. List them in your table in the appropriate columns.
3. In the *Explanation* column, explain why you classified the items as you did.

Analysis

1. How many elements did you find?
2. Which column has the greatest number of items? Is this the same for all students?

Mini LAB

Purpose Students learn to distinguish between elements, mixtures, and compounds.

Materials Science Journal, pen or pencil

Teaching Strategies

Have a class discussion on the items that students classified.

Have students classify the mixtures as either heterogeneous or homogeneous.

Analysis

1. Student responses will vary.
2. Student responses will vary.

Assessment

Content Have students work in groups of two or three to develop a picture book that explains the difference between elements, compounds, and mixtures. Use *Performance Assessment in the Science Classroom*, p. 169

Virtual Labs

Modeling How can molecular models be built?

Reading Strategy

Graphic Organizer Tell students to copy **Figure 6** in their notes, leaving some space to add more information and examples of each type of matter. They will use the graphic organizer as a way of making notes as they read the section. Have them look for the missing vocabulary words *colloid* and *suspension* and add them in the correct locations.

Teacher FYI

Phases Heterogeneous mixtures contain more than one phase. A phase is a region with uniform properties that has a boundary between itself and other areas of uniform properties. For example, the structure, heat capacity, and density of floating ice vary from the liquid water in which it is floating.

Discussion

Homogeneous Mixtures Remind students that the components of a homogeneous mixture are blended evenly throughout the mixture. Tell students that an alloy can be a solid homogeneous mixture of metals. How can two solid metals mix homogeneously? **The metals are melted, mixed as liquids, and then allowed to become solid again.** [L2] [IS] **Logical-Mathematical, Visual-Spatial**

Activity

Bag Project Bring four bags to class. Using large lettering, label the bags *Element*, *Compound*, *Homogeneous*, and *Heterogeneous*. Have students bring objects from home and place each one in the proper bag. After a week, empty the bags and discuss their contents and their classifications with the class. [L2] [ELL]

[IS] **Kinesthetic**

Visual Learning

Figure 7 Bring to class some aluminum foil, cereal with raisins, and liquid made from powdered, flavored drink mix dissolved in water. Have students classify these materials using the chart shown in **Figure 7**. **Aluminum foil is an element; raisin cereal is a heterogeneous mixture; powdered, flavored drink mix dissolved in water is a homogeneous mixture.** [L2] [IS] **Visual-Spatial, Kinesthetic**

✓ Reading Check

Answer a homogeneous mixture

Homogeneous Mixtures Remember that soft drink you like with your pizza? Some soft drinks contain water, sugar, flavoring, coloring, and carbon-dioxide gas.

Soft drinks in sealed bottles are examples of homogeneous mixtures. A **homogeneous** (hoh muh JEE nee us) **mixture** contains two or more gaseous, liquid, or solid substances blended evenly throughout. However, a soft drink in which you can see bubbles of carbon-dioxide gas and ice cubes is a heterogeneous mixture.

Vinegar is another homogeneous mixture. It appears to be clear, even though it is made up of particles of acetic acid mixed with water. Another name for a homogeneous mixture such as vinegar and a bottled soft drink is a solution. A **solution** is a homogeneous mixture of particles so small that they cannot be seen with a microscope and will never settle to the bottom of their container. Solutions remain constantly and uniformly mixed. The differences between substances and mixtures are summarized in **Figure 6**.

✓ **Reading Check** What kind of mixture is a solution?

Colloids Milk is an example of a specific kind of mixture called a colloid. Like a heterogeneous mixture, milk contains water, fats, and proteins in varying proportions. Like a solution, its components won't settle when it is left standing. A **colloid** (KAH loyd) is a type of mixture with particles that are larger than those in solutions but not heavy enough to settle out. The word *colloid* comes from a Greek word for *glue*. The first colloids studied were in gelatin, a source of some types of glue.

Paint is an example of a liquid with suspended colloid particles. Gases and solids can contain colloidal particles, too. For example, fog consists of particles of liquid water suspended in air, and smoke contains solids suspended in air.

Figure 6 All matter can be divided into substances and mixtures.

Curriculum Connection

Math Have students express the particle diameter given for solutions (0.000,000,001 m) in exponential notation. $1 \times 10^{-9} \text{ m}$ Then, ask them to calculate how many particles it would take to go across one cm. $1 \times 10^{-9} \text{ m} \times (100 \text{ cm}/1 \text{ m}) = 1 \times 10^{-7} \text{ cm/particle}$, then $1 \text{ cm} \times (1 \text{ particle}/1 \times 10^{-7} \text{ cm}) = 1 \times 10^7$ or 10,000,000 particles [L3] [IS] **Logical-Mathematical**

Figure 7 Fog is a colloid composed of water droplets suspended in air.

The light from the headlights is scattered by the fog.

The same colloid allows you to see the sunlight as it streams through the trees.

Detecting Colloids One way to distinguish a colloid from a solution is by its appearance. Fog appears white because its particles are large enough to scatter light as shown in **Figure 7**. Sometimes it is not so obvious that a liquid is a colloid. For example, some shampoos and gelatins are colloids called gels that appear almost clear. You can tell for certain if a liquid is a colloid by passing a beam of light through it, as shown in **Figure 8**. A light beam cannot be seen as it passes through a solution, but can be seen readily as it passes through a colloid. This occurs because the particles in the colloid are large enough to scatter light, but those in the solution are not. This scattering of light by colloidal particles is called the **Tyndall effect**.

Reading Check How can you distinguish a colloid from a solution?

Figure 8 Because of the Tyndall effect, a light beam is scattered by the colloid suspension on the right, but it passes invisibly through the solution on the left.

Use Science Words

Word Meaning Have students find out the names of colloids in which liquids contain liquids, liquids contain solids, and gases contain liquids or solids. **Colloids of liquids in liquids are emulsions, colloids of solids in liquids are sols (once cooled, they are called gels), colloids of liquids or solids in gases are called aerosols.** **L3** **IS** **Linguistic**

Fun Fact

The Tyndall effect is named after Irish scientist John Tyndall, who first described the effect in the mid-1800s.

Quick Demo
Tyndall Effect

Materials flashlight, clear drinking glass, water, milk

Estimated Time five minutes

Procedure Bring a small bright flashlight close to a clear drinking glass containing water. Have students observe the light on the wall as it passes through the water. Then add a couple drops of milk to the water and shine the light again. Ask students to name the light-scattering effect that they see. **the Tyndall effect** **L2**

Reading Check

Answer Pass a beam of light through it and check for the Tyndall effect.

Post Reading

Paired Learning In their own words have students explain to each other how the Tyndall Effect can be used to determine if something is a *colloid* or *solution*. Have them summarize the similarities and differences between these two types of matter that cause the effect. Encourage students to look back into the text if they cannot remember the details.

Active Reading

Learning Journal This strategy encourages students to interact with the reading, allowing personal responses. The left column entries can be research notes, lectures notes, or vocabulary terms. The right column entries are the student's response to, interpretation of, questions about, or analysis of the left column entries. **L2** **IS** **Linguistic, Visual-Spatial**

Differentiated Instruction

Challenge Ask students to determine the connection between beautiful red sunsets and suspensions. **The atmosphere around Earth has many suspended particles that scatter light. The more of these particles the light passes through, the redder the light appears. During a sunset, the Sun is low in the sky, so we see its light through a large number of scattering particles. Sunsets are particularly beautiful in years in which volcanic eruptions take place.** **L3** **IS** **Logical Mathematical**

Content Background

Another type suspension is found in the melt-water of glaciers. This water has an opaque appearance caused by suspended soil and rock particles that eventually settle out. Ask students what size the particles in meltwater must be. **greater than 100 nm**

Caption Answer

Figure 9 10 km

Figure 9 The mud deposited by the Mississippi River is thought to be more than 10,000 m thick.

Calculate in kilometers how thick the mud in the Mississippi River is.

3 Assess

DAILY INTERVENTION

Check for Understanding

Kinesthetic Place red food coloring, sand, milk, water, vinegar, and a clear drinking glass on a table. Allow students to mix these various substances in the order they choose. Have students write down observations and explain what qualities the mixtures exhibit after each addition of a new substance. [L2]

Linguistic, Visual-Spatial

Reteach

Compounds Place some NaCl and sand in a clear container and stir them together. Next, place some NaCl and water in a clear beaker and stir them together. Ask the class whether a new compound was formed in either process. **no** [L2]

Visual-Spatial

Assessment

Oral Burn a small sample of paper, and ask students to identify any elements, compounds, or mixtures. **element:** oxygen; **compounds:** carbon dioxide, the cellulose in the paper; **mixtures:** air, smoke particles in the air. Use PASC, p. 89.

[L2] **Visually Impaired** **Visual-Spatial, Kinesthetic**

Table 1 Comparing Solutions, Colloids, and Suspensions

Description	Solutions	Colloids	Suspensions
Settle upon standing?	no	no	yes
Separate using filter paper?	no	no	yes
Particle size	0.1–1 nm	1–1,000 nm	>1,000 nm
Scatter light?	no	yes	yes

Suspensions Some mixtures are neither solutions nor colloids. One example is muddy pond water. If pond water stands long enough, some mud particles will fall to the bottom, and the water clears. Pond water is a **suspension**, which is a heterogeneous mixture containing a liquid in which visible particles settle. **Table 1** summarizes the properties of different types of mixtures.

River deltas are large scale examples of how a suspension settles. Rivers flow swiftly through narrow channels, picking up soil and debris along the way. As a river widens, it flows more slowly. Suspended particles settle and form a delta at the mouth, as shown in **Figure 9**.

section 1 review

Summary

Pure Substances

- An element is a substance in which all atoms have the same identity.
- A compound is a substance that has two or more elements combined in a fixed proportion.

Mixtures

- A heterogeneous mixture is a mixture in which different materials can be distinguished easily.
- A homogeneous mixture contains two or more gaseous, liquid, or solid substances that are blended evenly throughout.
- Mixtures can be heterogeneous, homogeneous, colloids, or suspensions.

Self Check

1. **Describe** How is a compound similar to a homogeneous mixture? How is it different?
2. **Distinguish** between a substance and a mixture. Give two examples of each.
3. **Describe** the differences between colloids and suspensions.
4. **Think Critically** Why do the words “Shake well before using” indicate that a fruit juice is a suspension?

Applying Math

5. **Use Numbers** A polyester fabric is a mixture of 90 percent cotton and 10 percent polyester. If the fabric has a mass of 500 g, what is the mass of cotton in the fabric?

section 1 review

1. Both compounds and homogeneous mixtures are made of more than one element and are homogeneous. However, compounds must be made from elements in an exact ratio and involve chemical bonds between the elements in them.
2. A substance must be either an element or a compound. Mixtures can be made from combinations of compounds or elements.
3. Colloids do not settle out; suspensions eventually do settle out. Particles in colloids are smaller than particles in suspensions.
4. Materials in suspensions settle out.
5. 450 g

Comparing Pure Substances and Mixtures

Everything you see that is made of matter is either a pure substance or a mixture. Some things, such as iron nails and aluminum foil, are elements; others, such as water and salt, are compounds. Steel, lemonade, concrete, and a bowl of fruit are all examples of mixtures.

Real-World Problem

How do the properties of different pure substances and mixtures compare?

Goals

- **Classify** matter.
- **Calculate** density.
- **Compare** the properties of elements, compounds, and mixtures.

Materials

salt	magnet
iron filings	balance
pepper water	funnel
sugar water	filter paper
graduated cylinder	magnifying lens
250-mL beakers (5)	

Safety Precautions

Procedure

1. Copy the data table into your Science Journal.
2. **Determine** the color of each sample. Record all data in your table.
3. **Classify** the materials as an element, compound, or mixture.

Properties Table

Substance	Matter Classification	Color	Magnetic Attraction	Density
-----------	-----------------------	-------	---------------------	---------

4. **Determine** if each sample has a magnetic attraction.
5. **Determine** the mass of a 10 mL sample of each material. Calculate the density of each sample.
6. Try to separate the particles of the pepper/water mixture and the sugar water.
7. **Infer** if the different particles of each sample can be separated by using physical properties.

Conclude and Apply

1. **Describe** the separation methods of the mixture samples.
2. **Infer** how you can identify a substance as an element.
3. **Calculate** the density of each material.

Communicating Your Data

Identify experimental errors that might have occurred during the collection of your data.

LAB 559

Assessment

Content Have students test other matter samples such as concrete, copper wire, sugar, dry soup mix, and lemonade mix. Use PASC, p. 97

Communicating Your Data

As a class, discuss reasons for any differences in students' results. **L2** **IS** Logical-Mathematical

Real-World Problem

Purpose Students will identify samples of elements, compounds, and mixtures.

Process Skills observe, measure, use data tables, compare and contrast, infer

Time Required 45 minutes

Procedure

Alternate Materials copper wire, aluminum foil, sugar, pepper, lemonade, soil/water mixture

Safety Precautions Have students wear safety goggles. Warn students that hot and cold glasses appear the same.

Teaching Strategies Prepare the five samples of matter in small beakers before the activity.

Troubleshooting Be certain all the sugar dissolves in the water samples by using hot tap water and only 1–2 g of sugar.

Conclude and Apply

1. The salt and iron filings are easily separated by using a magnet to attract the filings, and the pepper is easily filtered out of the water. Students will not be able to separate the sugar from the solution.
2. All elements are listed on the periodic table of the elements.
3. iron filings—1.94 g/mL
table salt—1.32 g/mL
sugar water—1.0 g/mL
pepper in water—1.0 g/mL

Properties of Matter

Section Focus Transparency All that Glitters

If you imagine a 19th century gold miner, you may think of someone standing in a river swirling water in a pan. Panning was a common technique used to separate gold from a mixture of sand and gravel.

1. What properties of gold allow it to be separated from sand and gravel by panning?
2. How does gold change from the time it is collected to the time it is ready to sell?

L2

Reading Preview

Tie to Prior Knowledge

Visiting Places Ask students to describe, without naming it, a place that they have visited. As others try to determine the site, remind students that any description, whether of matter or of a place, requires careful attention to important properties. L1 Visual-Spatial

Content-Specific Words Have students use the text to find the meaning of the new vocabulary terms. Ask them to create cartoons that describe each of the words. For *physical change* they may draw a girl with straight hair; for *chemical change* they may draw brown hair to blond hair.

Reading Guide

What You'll Learn

- Identify substances using physical properties.
- Compare and contrast physical and chemical changes.
- Identify chemical changes.
- Determine how the law of conservation of mass applies to chemical changes.

Why It's Important

Understanding chemical and physical properties can help you use materials properly.

Review Vocabulary

state of matter: one of three physical forms of matter: solid, liquid, or gas

New Vocabulary

- physical property
- physical change
- distillation
- chemical property
- chemical change
- ★ law of conservation of mass

Physical Properties

You can stretch a rubber band, but you can't stretch a piece of string very much, if at all. You can bend a piece of wire, but you can't easily bend a matchstick. In each case, the materials change shape, but the identity of the substances—rubber, string, wire, and wood—does not change. The abilities to stretch and bend are physical properties. Any characteristic of a material that you can observe without changing the identity of the substances that make up the material is a **physical property**. Examples of other physical properties are color, shape, size, density, melting point, and boiling point. What physical properties can you use to describe the items in **Figure 10**?

Figure 10 Appearance is the most obvious physical property. Describe the appearance of these items.

Appearance How would you describe a tennis ball? You could begin by describing its shape, color, and state of matter. You might describe the tennis ball as a brightly colored, hollow sphere. You can measure some physical properties, too. For instance, you could measure the diameter of the ball. What physical property of the ball is measured with a balance?

To describe a soft drink in a cup, you could start by calling it a liquid with a brown color. You could measure its volume and temperature. Each of these characteristics is a physical property of that soft drink.

Figure 11 The best way to separate substances depends on their physical properties. Size is the property used to separate poppy seeds from sunflower seeds in this example.

Behavior Some physical properties describe the behavior of a material or a substance. As you might recall, objects that contain iron, such as a safety pin, are attracted by a magnet. Attraction to a magnet (magnetism) is a physical property of the substance iron. Every substance has a specific combination of physical properties that make it useful for certain tasks. Some metals, such as copper, can be drawn out into wires. Others, such as gold, can be pounded into sheets as thin as 0.1 micrometers (μm), about 4-millionths of an inch. This property of gold makes it useful for decorating picture frames and other objects. Gold that has been beaten or flattened in this way is called gold leaf.

Think again about your soft drink. If you spill it, the drink will spread out over the table or floor. If you knock over a jar of molasses, however, it does not flow as easily. The ability to flow is a physical property of liquids.

Using Physical Properties to Separate Removing the seeds from a watermelon can be easily done based on the physical properties of the seeds compared to the rest of the fruit. **Figure 11** shows a mixture of poppy seeds and sunflower seeds. You can identify the two kinds of seeds by differences in color, shape, and size. By sifting the mixture, you could separate the poppy seeds from the sunflower seeds quickly because their sizes differ.

Now look at the mixture of iron filings and sand shown in **Figure 11**. You probably wouldn't be able to sift out the iron filings because they are similar in size to the sand particles. What you could do is pass a magnet through the mixture. The magnet will attract only the iron filings and pull them from the sand. This is an example of how a physical property, such as magnetic attraction, can be used to separate substances in a mixture. Something like this is done to separate iron for recycling.

Reading Check What physical properties could be used to separate two different substances?

Magnetism easily separates iron from sand.

Recycling and Physical Properties Recycling conserves natural resources. In some large recycling projects, aluminum metal must be separated from scrap iron. What physical properties of the two metals could be used to separate them?

Text Question Answer

size, shape, color, surface, density, mass

Text Question Answer

Mass could be measured with a balance.

Caption Answer

Figure 10 The ball is spherical, fuzzy, all one color, and has a curved line on it. The rock is rough, has many colors, has several dark straight lines, and has an irregular shape.

Recycling and Physical Properties

Since metallic iron is magnetic and metallic aluminum is not, strong magnets could attract iron from a mixture of iron and aluminum.

Quick Demo

Chemical Change

Materials beaker, candle, matches

Estimated Time 4 minutes

Procedure Hold the bottom of a glass beaker directly over a burning candle for a few minutes. What clues indicate that a chemical change has taken place? Carbon deposits begin to form on the outside of the beaker caused by the breakdown of the hydrocarbon candle wax. Carbon is released from its bonds with other carbon and hydrogen atoms. **L2** **Visual-Spatial, Kinesthetic**

Answer color, shape, size, magnetism

Differentiated Instruction

Challenge Tell students that viscosity is a measure of a fluid's resistance to flow. Have students contact a service station or an auto parts store and ask about viscosity ratings of motor oils. Higher viscosity oils have more resistance to flow and are used in warm weather, while lower viscosity motor oils flow more easily and are used in cold temperatures. **L3**

Logical-Mathematical

Learning Disabled Bring a magnet and some iron filings to class. Prepare a mixture of the iron filings and sugar. Ask students how they know the mixture is not the result of a chemical change, and how the mixture can be separated. The mixture looks like the components from which it was made; add water to dissolve the sugar but not the iron, or use a magnet to separate the iron from the sugar particles. **L1**

Kinesthetic, Visual-Spatial

✓ Reading Check

Answer No, the identity of the element or compound remains the same.

Mini LAB

Purpose Students will use physical change to separate the colors in black ink. **L2** **ELL**

COOP LEARN

Materials black marker (not permanent), coffee filter or filter paper, water, plate, eyedropper, Science Journal, pen or pencil

Teaching Strategies

Have students use different brands of black markers and black felt-tip pens.

Remind students to handle the coffee filter as little as possible. The oil from their fingers will distort the results. **IC** **3**

Analysis

physical change

Assessment

Oral Ask students what colors were mixed together to make the black ink. *Answers will vary based on the ink used.* Use **Performance Assessment in the Science Classroom**, p. 89 **L2**

Figure 12 state of matter

Mini LAB

Separating Ink

Procedure **IC** **3** **4**

1. Cut a circle out of a **clean, white coffee filter** with a 9-cm diameter. Draw a spot using a **nonpermanent black marker** in the center of the filter.
2. Place the filter on a **plate**. Using a **dropper**, place ten drops of water on the spot.

Analysis

Make a labeled drawing of your results in your **Science Journal**. What type of change did you observe? Explain.

Physical Changes

If you break a piece of chewing gum, you change some of its physical properties—its size and shape. However, you do not change the identity of the materials that make up the gum.

The Identity Remains the Same When a substance freezes, boils, evaporates, or condenses, it undergoes physical changes. A change in size, shape, or state of matter is called a **physical change**. Such a change might involve energy changes, but the kind of substance—the identity of the element or compound—does not change. Because all substances have distinct properties, such as densities, specific heats, and boiling and melting points, which are constant, these properties can be used to help identify them when a particular mixture contains substances that are not yet identified.

✓ Reading Check Does a change in state mean that a new substance has formed? Explain.

Iron is a substance that can change states if it absorbs or releases enough energy; at high temperatures, it melts. However, in both the solid and liquid state, iron has physical properties that identify it as iron. Color changes can accompany a physical change, too. For example, when iron is heated, it first glows red. Then, if it is heated to a higher temperature, it turns white, as shown in **Figure 12**.

Using Physical Change to Separate A cool drink of water is something most people take for granted, but in some parts of the world, drinkable water is scarce. Not enough drinkable water can be obtained from wells. Many such areas that lie close to the ocean obtain drinking water by using the physical properties of water to separate it from the salt. One separation method, which uses the property of boiling point, is distillation.

Figure 12 Heating iron raises its energy level and changes its color. These energy changes are physical changes because the substance is still iron.

Define When liquid water becomes a solid, what type of physical change occurs?

LAB DEMONSTRATION

Purpose to determine whether an observed change is chemical or physical

Materials water, potassium permanganate, sodium hydrogen sulfite, 250-mL beaker, stirring rod

Procedure Add water to the beaker until it is half full. Add a crystal of potassium per-

manganate to the water. Add 1 g of sodium hydrogen sulfite to the solution and stir until the solution becomes colorless.

Expected Outcome The addition of sodium hydrogen sulfite to potassium permanganate in water will cause a change in color.

Assessment

Is dissolving a chemical or physical change? **physical change** What evidence of a chemical change did you see? *The change in color from purple to colorless indicated that new substances were being formed.*

Distillation The process used for separating substances in a mixture by evaporating a liquid and recondensing its vapor is **distillation**. It usually is done in the laboratory using an apparatus similar to that shown in **Figure 13**. The liquid vaporizes and condenses, leaving the solid material behind.

Two liquids having different boiling points can be separated in a similar way. The mixture is heated slowly until it begins to boil. Vapors of the liquid with the lowest boiling point form first and are condensed and collected. Then, the temperature is increased until the second liquid boils, condenses, and is collected. Distillation is used often in industry. Natural oils such as mint are distilled.

Figure 13 Distillation can easily separate liquids from solids dissolved in them. The liquid is heated until it vaporizes and moves up the column. Then, as it touches the water-cooled surface of the condenser, it becomes liquid again.

Chemical Properties and Changes

You probably have seen warnings on cans of paint thinners and lighter fluids for charcoal grills that say these liquids are flammable (FLA muh buhl). The tendency of a substance to burn, or its flammability, is an example of a chemical property. Burning produces a new substance during a chemical change. A **chemical property** is a characteristic of a substance that indicates whether it can undergo a certain chemical change. Many substances used around the home, such as lighter fluids, are flammable. Knowing which ones are flammable helps you to use them safely.

A less-dramatic chemical change can affect some medicines. Look at **Figure 14**. You probably have seen bottles like this in a pharmacy. Many medicines are stored in dark bottles because they contain compounds that can change chemically if they are exposed to light.

Figure 14 The brown color of these bottles tells you that these vitamins may react to light. Reaction to light is a chemical property.

Visual Learning

Figure 14 Review with students the distillation process, and ask a volunteer to trace the path of water through the apparatus shown in the figure. Explain that the distillate moves through the inner portion of the condenser, while cold water, which helps cool the distillate, runs through the outer portion. **L2** **Visual-Spatial**

Curriculum Connection

History Compounds called nitrates played a major role in the history of Chile. Have students find out what chemical property makes nitrates important and what role they played in Chile. **Nitrates are one component of explosives. Nitrates were Chile's largest export in the late 1800s, giving the country money for economic development. The nitrate market collapsed during World War I, when chemists discovered a way to synthesize nitrates.** **L3** **Linguistic**

Make a Model

Magnetism and Iron Turn a shoe-box lid upside down and place iron filings and sand in the lid. Place a bar magnet underneath the lid and move it around while holding it against the bottom of the lid. Observe how the iron filings are both attracted and repulsed by the magnet depending upon the position of magnet. **Visual-Spatial**

Activity

Element Properties Ask students to pick a chemical element and use an encyclopedia or Internet source to make a list of its properties. Have them then divide the list into chemical and physical properties. **L2** **ELL**

Linguistic

Discussion

Flammability What is involved in determining the flammability of a substance? Some of the factors used to determine flammability are temperature, vapor concentration, and ability to sustain combustion. Air is usually considered the oxidant in these measurements.

Fun Fact

Air, or oxygen, is not the only oxidant required for a substance to burn, there are also substances that will burn in fluorine gas.

Reading Strategy

Fix-Up Strategy Read aloud to students the text on distillation while interjecting questions about how you make sense of text as you read. Show students how to use the related illustration, **Figure 13**, to help unlock the text. Then, have students find their own difficult passages and practice close reading with a partner.

Alchemy Even though most people connect alchemy with the middle ages, alchemy started many years before that. References to alchemy can be found in Chinese, Egyptian, and Arabian histories.

Research Have students select and research a culture that has played a role in alchemy. Have students present their findings.

✓ Reading Check

Answer a change of one substance to another

Caption Answer

Figure 15 formation of bubbles or solids, heat, cooling

Inquiry Lab

Oxidation and Food

Purpose to demonstrate chemical reactions in common foods

Possible Materials potato, lemon juice, peach, pear, apple, bowls (2)

Teaching Strategies

- Cut the potato, peach, pear, and apple in half. Dip the exposed inner surface of one of the food items in the lemon juice, then place in bowl.
- Place the other half in another bowl and allow both items to sit for 30 minutes. Encourage students to explain the reactions that occurred and allow them to explore other questions that arise. L2 IS **Kinesthetic, Visual-Spatial**

For additional inquiry activities, see *Science Inquiry Lab Manual*.

Alchemy In the Middle Ages, alchemy was an early form of chemistry devoted to the study of changing baser metals into gold and also to finding the elixir of perpetual youth. Based on what we know now about the properties of metals and biology, it is easy to understand why this field of study is no longer practiced.

Detecting Chemical Changes

If you leave a pan of chili cooking unattended on the stove for too long, your nose soon tells you that something is wrong. Instead of a spicy aroma, you detect an unpleasant smell that alerts you that something is burning. This burnt odor is a clue that a new substance has formed.

The Identity Changes The smell of rotten eggs and the formation of rust on bikes or car fenders are signs that chemical changes have taken place. A change of one substance to another is a **chemical change**. The foaming of an antacid tablet in a glass of water and the smell in the air after a thunderstorm are other signs of new substances being produced. In some chemical changes, a rapid release of energy—detected as change of heat, light, and/or sound production—is a clue that changes are occurring.

✓ Reading Check What is a chemical change?

A clue such as heat, cooling, or the formation of bubbles or solids in a liquid is a helpful indicator that a chemical reaction is taking place. However, the only sure proof is that a new substance is produced. Consider the following example. The heat, light, and sound produced when hydrogen gas combines with oxygen in a rocket engine are clear evidence that a chemical reaction has taken place. But no clues announce the reaction that takes place when iron combines with oxygen to form rust because the reaction takes place so slowly. The only clue that iron has changed into a new substance is the presence of rust. Burning and rusting are chemical changes because new substances form. You sometimes can follow the progress of a chemical reaction visually. For example, you can see lead nitrate forming in **Figure 15**.

Figure 15 The solid forming from two liquids is another sign that a chemical reaction has taken place.

Identify clues that show a reaction has taken place.

564 CHAPTER 18 Classification of Matter

Science Journal

Chemical Changes in Daily Life Have students keep a log of chemical changes they encounter in a 24-hour period. The logs should describe each change and list clues that helped students conclude that the change was chemical. **Answers could include:** respiration—oxygen used, carbon dioxide released; combusting gasoline—carbon dioxide produced, heat released; cooking—an egg becomes white and solid. L2 P

IS **Linguistic, Visual-Spatial**

IDENTIFYING Misconceptions

Matter Conservation Students may think that matter is not conserved in physical or chemical changes. Refer to page F at the beginning of this chapter for teaching strategies that address this misconception.

✓ Reading Check

Answer The mass of all substances present before a chemical change equals the mass of all the substances remaining after the change.

Applying Math

Math Standards

National: 1, 2, 9

Florida: MA.A.3.41

Teaching Strategy

Have students count the atoms of each type of element. The number is the same on both sides of the equation. The total number of atoms of reactants will equal the total number of atoms of products. In the example, there are a total of four atoms: two hydrogens on each side. L2

 **Logical-Mathematical**

Answers to Practice Problems

- $(24 \text{ g CH}_4 + 96 \text{ g O}_2) =$
 $(66 \text{ g CO}_2 + x \text{ g H}_2\text{O})$
 $120 \text{ g} = 66 \text{ g} + x \text{ g H}_2\text{O}$
 $120 \text{ g} - 66 \text{ g} = 54 \text{ g H}_2\text{O}$
- $(54 \text{ g Al} + 409.2 \text{ g ZnCl}_2) =$
 $(196.2 \text{ g Zn} + x \text{ g AlCl}_3)$
 $463.2 \text{ g} = 196.2 \text{ g} + x \text{ g AlCl}_3$
 $463.2 \text{ g} = 196.2 \text{ g} + 267 \text{ g AlCl}_3$

Science Online

Topic: Caves

Visit fl.gpscience.com for Web links to information about cave formations.

Activity Describe the formation of stalactites and stalagmites. Explain the differences between the two and whether they are the result of a physical and/or chemical process.

Chemical In other cases, the change is chemical. For example, solid calcium carbonate, a compound that mostly makes up limestone, does not dissolve easily in water. However, when the water is even slightly acidic, as it is when it contains some dissolved carbon dioxide, calcium carbonate reacts. It changes into a new substance, calcium hydrogen carbonate, which does dissolve in water. This change in limestone is a chemical change because the identity of the calcium carbonate changes. The White Cliffs of Dover, shown on the right in **Figure 16**, are made of limestone and undergo such chemical changes, as well as physical changes. A similar chemical change produces caves and the icicle-shaped rock formations that often are found in them.

Applying Math Calculate

THE LAW OF CONSERVATION OF MASS When a chemical reaction takes place, the total mass of reactants equals the total mass of products. If 18 g of hydrogen reacts completely with 633 g of chlorine, how many grams of HCl are formed? $\text{H}_2 + \text{Cl}_2 \rightarrow 2\text{HCl}$

IDENTIFY known values and the unknown value

Identify the known values:

$$\text{mass of H}_2 = 18 \text{ g}$$

$$\text{mass of Cl}_2 = 633 \text{ g}$$

$$\text{mass of reactants} = \text{mass of products}$$

Identify the unknown value:

$$\text{mass of HCl} \xrightarrow{\text{means}} ? \text{ g}$$

SOLVE the problem

$$\text{Solve for the mass of HCl.} \quad \text{g H}_2 + \text{g Cl}_2 = \text{g HCl}$$

$$\text{Substitute the known values.} \quad 18 \text{ g} + 633 \text{ g} = 651 \text{ g HCl}$$

CHECK the answer

Does your answer seem reasonable? Check your answer by subtracting the mass of H_2 from the mass of HCl. Do you obtain the mass of the Cl_2 ? If so, the answer is correct.

Practice Problems

- In the following reaction, 24 g of CH_4 (methane) reacts completely with 96 g of O_2 to form 66 g of CO_2 . How many grams of H_2O are formed? $\text{CH}_4 + 2\text{O}_2 \rightarrow \text{CO}_2 + 2\text{H}_2\text{O}$
- In the following equation, 54.0 g of Al reacts completely with 409.2 g of ZnCl_2 to form 196.2 g of Zn metal. How many grams of AlCl_3 are formed? $2\text{Al} + 3\text{ZnCl}_2 \rightarrow 3\text{Zn} + 2\text{AlCl}_3$

For more practice problems go to page 879, and visit Math Practice at fl.gpscience.com.

Teacher FYI

Changing Limestone The weathering of Dover's white cliffs involves the breakdown of limestone into soluble compounds. The formation of stalactites in caves involves the precipitation of limestone from water solutions. Thus, the formation of stalactites is the reverse of the weathering of the cliffs of Dover.

Post Reading

Cooperative Learning Working in small groups, have students create a chart with the headings *Grand Canyon*, *Sinkholes*, *Sand Beaches*, and *Rock Formations*. Have them list physical and chemical changes that contributed to the formation of each. Encourage students to find pictures or interesting facts to add to their charts.

The Conservation of Mass

Wood is combustible, or burnable. As you just learned, this is a chemical property. Suppose you burn a large log in a fireplace, as shown in **Figure 17**, until nothing is left but a small pile of ashes. Smoke, heat, gas, and light are given off, and the changes in the appearance of the log confirm that a chemical change took place. You might think that matter was lost during this change because the pile of ashes looks much smaller than the log did. In fact, the mass of the ashes is less than that of the log. Suppose that you could collect all the oxygen in the air that was combined with the log during the burning and all the smoke, heat, light, and gases that escaped from the burning log and measure their masses, too. Then you would find that no mass was lost after all.

Not only is no mass lost during burning, mass is not gained or lost during any chemical change. In other words, matter is neither created nor destroyed during a chemical change. According to the **law of conservation of mass**, the mass of all substances that are present before a chemical change equals the mass of all the substances that remain after the change.

Figure 17 This reaction appears to be destroying these logs. When it is over, only ashes will remain. Yet you know that no mass is lost in a chemical reaction.

Explain why this is so.

Reading Check Explain what is meant by the law of conservation of mass.

section 2 review

Summary

Physical Properties

- You can observe physical properties without changing the identity of a substance.

Physical Changes

- Change in the size, shape, or state of matter is a physical change.

Chemical Properties and Changes

- A chemical property is a characteristic of a substance that indicates whether it can undergo a certain chemical change.
- A change of one substance to another is a chemical change.
- Many metals are separated from their ores and purified using chemical changes.

Self Check

1. **Explain** why evaporation of water is a physical change and not a chemical change.
2. **List** four physical properties you could use to describe a liquid.
3. **Describe** why flammability is a chemical property rather than a physical property.
4. **Explain** how the law of conservation of mass applies to chemical changes.
5. **Think Critically** How might you demonstrate the law of conservation of mass for melting ice and distilling water?

Applying Math

6. **Calculate** In the following equation, 417.96 g of Bi (bismuth) reacts completely with 200 g of F (fluorine). How many grams of BiF₃ (bismuth fluoride) are formed? $2 \text{ Bi} + 3 \text{ F}_2 \rightarrow 2 \text{ BiF}_3$

section 2 review

1. The makeup of the water units is unchanged.
2. color, odor, volume, temperature
3. Because the original materials are changed into new substances.
4. The mass of all substances present before a chemical change equals the mass of all the substances remaining after the change.
5. Let the ice melt on a balance, and show that the balance doesn't move.

Find the mass of the liquid water, boil it and collect the condensed vapor and any solids. Find the mass of the condensed vapor and solids.

6. 617.96 g

Caption Answer

Figure 17 Some of the log's components combine with oxygen to form gases.

3 Assess

DAILY INTERVENTION

Check for Understanding

Kinesthetic Have a student light a match and allow it to burn. Also, place an ice cube in a glass container and allow it to melt. Have students explain what type of changes took place with each item and describe the final properties of each. **L2** **IS** **Visual-Spatial**

Reteach

Mass Place a small, open vial of dilute silver nitrate solution carefully inside a large flask containing a dilute solution of sodium chloride. Determine the mass of the entire assembly. Then tip the flask to intentionally spill the contents of the small vial. A white precipitate will quickly form. Re-mass the assembly. Ask students what law is demonstrated when the two masses are in agreement. **law of conservation of mass** **L2** **ELL**

IS **Visual-Spatial, Kinesthetic**

Assessment

Oral Display several similar but slightly different candles. Have a student describe each candle using a minimum number of physical properties. Other students must identify the candle from its physical properties. Use **Performance Assessment in the Science Classroom**, p. 89. **L1**

Real-World Problem

Purpose Students will design an experiment to observe the law of conservation of mass.

Process Skills observe, measure, use and make data tables, collect and organize data, communicate, form hypotheses, infer

Time Required 45 minutes

Procedure

Possible Materials Different brands of antacid tablets and different sized plastic drink bottles can be used.

Safety Precautions Caution students never to eat or drink anything during science class.

Form a Hypothesis

Possible Hypothesis Students should hypothesize that the mass of the reactants should be approximately equal to the mass of the products.

Test Your Hypothesis

Possible Procedures Students can use a mortar and pestle to grind the antacid tablets. The powdered tablet is placed into a dry balloon. Students should measure the mass of the balloon bottle with water before and after the reaction. The balloon should be fitted over the mouth of the bottle. The powder will be poured into the bottle, then gently swirled.

Goals

- **Measure** the total mass of water and antacid tablets before and after the tablets are dissolved in the water.
- **Compare** the total mass of water and tablets before and after the tablets are dissolved in the water.
- **Infer** whether or not the law of conservation of mass applies to antacid tablets dissolving in water

Possible Materials

antacid tablets
empty plastic drink bottle
balloon
beaker
water
spatula
balance
mortar
pestle
funnel

Safety Precautions

Do not eat the antacid tablet.

Measuring the Conservation of Mass

Real-World Problem

Have you ever watched burning logs in a fireplace? If you have, you might have noticed many large logs being burned in the hearth during an evening. At the end of the night, nothing more than a pile of ash remains. In this lab, your group will design an experiment to demonstrate the law of conservation of mass. Is the mass of antacid tablets conserved after they are dissolved?

Form a Hypothesis

Based on your understanding of mass conservation, form a hypothesis that predicts the total mass of antacid tablets and water before and after the tablets are dissolved.

Test Your Hypothesis

Make a Plan

1. As a group, agree upon and write the hypothesis statement.
2. Decide upon any safety equipment you need or safety procedures you need to devise to ensure the safety of your group during the experiment.

Alternative Inquiry Lab

Open and Closed Systems To make this Lab into an Inquiry Lab, have students compare the initial and final masses of an open system and closed system. They can create a closed system by following the procedure they devised during their lab, and they can create an open system by placing the powder directly into the bottle and leaving the container open.

Students can also research the chemical reactions involved when antacids are used to neutralize excess stomach acid. Citric acid ($C_6H_8O_7$) and sodium bicarbonate ($NaHCO_3$) are the main ingredients in antacid tablets. When the tablets are dropped into water with dissolved H^+ ions, a chemical reaction occurs to produce water and carbon dioxide.

Using Scientific Methods

3. **Plan** an experiment to test your hypothesis. List the steps of your experiment.
4. **List** the materials you need to test your hypothesis.
5. Have one group member reread your entire experiment aloud to the group to make certain you have all the necessary materials and that your experimental steps can be easily followed.

Data Table

Trial Number	Mass Before Reaction	Mass After Reaction

Follow Your Plan

1. Make sure your teacher approves your plan.
2. Copy the data table into your Science Journal to record measurements.
3. While doing the experiment, write your observations, and complete the data table in your Science Journal.

Analyze Your Data

1. **Describe** the effects of the chemical reaction between the antacid powder and the water.
2. **Compare** the total mass of the substances before the reaction to their mass after the reaction.
3. **Graph** the mass of the substances before and after the reaction using a bar graph.
4. **Explain** if your data supported your hypothesis.

Conclude and Apply

1. **Identify** possible experimental errors in your experiment design.
2. **Infer** how mass might have been lost or added between the initial and final weighing of the substances.
3. **Infer** what the expected mass of the substances should be after the chemical reaction occurred.

Communicating Your Data

Compare the data your group collected with the data collected by the other groups and discuss possible reasons for differences in the data

LAB 569

Assessment

Content Have students write and act out a skit demonstrating the law of conservation of mass at work during a chemical reaction such as paper burning or the joining of two elements to form a compound. Use PASC, p. 147.

Communicating Your Data

Encourage students to create data tables and bar graphs electronically.

Teaching Strategies

- Explain that the mass of the system before the reaction will probably not be exactly the same as the mass after the reaction due to some form of experimental error. There is always some margin of error during an experiment.

Troubleshooting One student needs to stretch the balloon's opening while a second student scoops the powdered tablet into the balloon. Make certain the plastic bottle and attached balloon will fit on your classroom balances.

Expected Outcome Although the initial mass and final mass of the substances may not be identical, the mass of the reactants should be nearly equal to the mass of the products. A small amount of mass will probably be lost due to experimental error.

Analyze Your Data

1. The water will fizz vigorously, and the balloon will partially inflate with released carbon dioxide.
2. Results will vary depending upon the measurements collected by each group.
3. Graphs will vary.
4. Answers will vary.

Error Analysis Discuss with students possible errors in their data. Students might make inaccurate measurements, or gases produced during the reaction might escape.

Conclude and Apply

1. Answers may vary.
2. Answers may vary.
3. Answers may vary.

Content Background

Scientists constantly attempt to create or discover new elements. Recently discovered elements do not exist in nature but have been synthesized by bombarding existing elements with high-speed particles. The element seaborgium was synthesized by bombarding the element californium by highly accelerated oxygen nuclei.

Discussion

Oxygen The element oxygen makes up 46 percent of Earth's crust, yet it makes up only 21 percent of Earth's atmosphere. Most oxygen is contained in compounds. For example, sand is silicon dioxide, SiO_2 .

Activity

Changing Elements Unless an element is radioactive and its nucleus changes, each atom remains the same element. However, elements change form and location. Provide students with the following statements. Have them draw an illustration that uses arrows and the statements to show how the element nitrogen is cycled on Earth. Statements:

- Plants obtain nitrogen from the soil.
- Bacteria on certain plants change atmospheric nitrogen to a useful form.
- Animals eat plants.
- Animals and plants die and decompose.

L2  Visual-Spatial, Logical-Mathematical

Intriguing Elements

Did you know...

... **Silver-white cobalt**, which usually is combined with other elements in nature, is used to create rich paint pigments. It can be used to form powerful magnets, treat cancer patients, build jet engines, and prevent disease in sheep.

... Gold is the most ductile

(stretchable) of all the elements. Just 29 g of gold—about ten wedding bands—can be pulled into a wire 100 km long. That's long enough to stretch from Toledo, Ohio, to Detroit, Michigan, and beyond.

Percent of Elements in the Human Body

... Zinc makes chewing gum taste better.

Up to 0.3 mg of zinc acetate can be added per 1000 mg of chewing gum to provide a tart, zingy flavor.

Applying Math

- Zinc acetate is approximately 35 percent zinc. How many grams of chewing gum would be needed to provide a total of 10.0 mg of zinc?
- If you wanted to produce a gold wire with the same diameter as mentioned in the example above, how many grams would be needed to make a wire one meter in length?
- Table sugar has the chemical formula $\text{C}_{12}\text{H}_{22}\text{O}_{11}$. If you were going to build a scale model of sucrose (table sugar) and you had 36 model carbon atoms, how many of each of the others (hydrogen and oxygen) would you need to build an accurate, complete sucrose model?

570 CHAPTER 18 Classification of Matter

Applying Math

Teaching Strategies

- Review with students how to set up a proportion. Remind students that 1,000 mg equals 1 g.
- Discuss with students that they need to convert meters to kilometers or kilometers to meters in order to set up a proportion to solve.

- Review ratios with students to determine the scale factor, 3.

Answers

- about 33 g
- 0.00029 g
- H—66 atoms; O—33 atoms

 MAA.3.4.1,

Reviewing Main Ideas

Section 1 Composition of Matter

1. Elements and compounds are substances. A mixture is composed of two or more substances.
2. You can distinguish between the different materials in a heterogeneous mixture using either your unaided eye or a microscope.
3. Colloids and suspensions are two types of heterogeneous mixtures. The particles in a suspension will settle eventually. Particles of a colloid will not. Milk is an example of a colloid.
4. In a homogeneous mixture, the particles are distributed evenly and are not visible, even when using a microscope. Homogeneous mixtures can be composed of solids, liquids, or gases.
5. A solution is another name for a homogeneous mixture that remains constantly and uniformly mixed.

Best if Sold by Above Date
Shake Well for Best Taste

This is a clear indication that this mixture is a suspension.

Section 2 Properties of Matter

1. Physical properties are characteristics of materials that you can observe without changing the identities of the substances.
2. Chemical properties indicate what chemical changes substances can undergo. Many medicines are stored in dark bottles because they react with light.
3. In physical changes, the identities of substances remain unchanged.
4. In chemical changes, the identities of substances change; new substances are formed. A visible chemical change takes place when rust is cleaned with bleach.

5. The law of conservation of mass states that during any chemical change, matter is neither created nor destroyed.

FOLDABLES Use the Foldable that you made at the beginning of the chapter to help you review the classification of matter.

Reviewing Main Ideas

Summary statements can be used by students to review the major concepts of the chapter.

★ FCAT Vocabulary

Complete each sentence with the correct vocabulary word or words.

1. Substances formed from atoms of two or more elements are called _____.
2. A(n) _____ is a heterogeneous mixture in which visible particles settle.
3. Freezing, boiling, and evaporation are all examples of _____.
4. According to the _____, matter is neither created nor destroyed during a chemical change.
5. A mixture in which different materials are easily identified is _____.
6. Compounds are made from different atoms of two or more _____.
7. Distillation is a process that can separate two liquids using _____.

Checking Concepts

Choose the word or phrase that best answers the question.

8. Bending a copper wire is an example of what property?

A) chemical	C) element
B) conservation	D) physical

9. Which is NOT an element?

A) carbon	C) oxygen
B) hydrogen	D) water
10. Which is an example of a chemical change?

A) boiling	C) evaporation
B) burning	D) melting
11. What is gelatin?

A) colloid	C) substance
B) compound	D) suspension
12. Which is an example of a visible sunbeam?

A) an element	C) a compound
B) a solution	D) the Tyndall effect
13. How would you classify the color of a rose?

A) chemical change
B) chemical property
C) physical change
D) physical property
14. How would you describe the process of evaporating water from seawater?

A) chemical change
B) chemical property
C) physical change
D) physical property
15. Which is a substance?

A) colloid	C) mixture
B) element	D) solution
16. Which property can be used to help identify an unknown substance?

A) specific heat	C) temperature
B) combustion	D) Tyndall effect
17. Which statement about the law of conservation of mass is TRUE?

A) Mass is created only.
B) Mass is created and destroyed.
C) Mass is destroyed only.
D) Mass is neither created nor destroyed.

Interpreting Graphics

18. Copy and complete the concept map below about matter.

Use the table below to answer question 19.

Common Colloids

Colloid	Example
Solid in a liquid	Gelatin
Solid in a gas	
Gas in a solid	
Solid in a liquid	
Liquid in a gas	

19. **Identify** how different colloids can involve different states. For example, gelatin is formed from solid particles in a liquid. Complete the table using these colloids: *smoke, marshmallow, fog, and paint*.

Thinking Critically

20. **Compare and contrast** elements and compounds. Give two examples of each.
21. **Explain** Carbon and the gases hydrogen and oxygen combine to form sugar. How do you know sugar is a compound?

22. Use a nail rusting in air to explain the law of conservation of mass.
23. **Use Variables, Constants, and Controls** Marcos took a 100-cm³ sample of a suspension, shook it well, and poured equal amounts into four different test tubes. He placed one test tube in a rack, one in hot water, one in warm water, and the fourth in ice water. He then observed the time it took for each suspension to settle. What was the variable in the experiment? What was one constant?
24. **Concept Map** Make a network tree to show types of liquid mixtures. Include these terms: *homogeneous mixtures, heterogeneous mixtures, solutions, colloids, and suspensions*.

Applying Math

Use the graph below to answer question 25.

25. **Use Proportions** If you had 50 atoms of hydrogen, how many atoms each of oxygen, carbon, and nitrogen would you need to have the elements in the same proportion as they are in your body?
26. **Use Numbers** In the following equation, 243.5 g of Sb (antimony) reacts completely with 1000 g of I₂ (iodine) to form 1004.9 g of SbI₃ (antimony triiodide). How many grams of I₂ were consumed in the reaction? $2 \text{ Sb} + 3 \text{ I}_2 \rightarrow 2 \text{ SbI}_3$

Thinking Critically

20. Elements and compounds are made from atoms. An element has all the same atoms whereas a compound is made of atoms of two or more elements. Accept all reasonable examples of elements and compounds.
21. It can't be separated by physical means; it looks different from the elements that make it up.
22. The combined mass of the oxygen and the iron before the reaction is equal to the mass of the rust after the reaction.
23. The variable was temperature. One constant was the amount of suspension put into each tube.
24. Mixtures include homogeneous mixtures, which are solutions, and heterogeneous mixtures, which include colloids or suspensions.

Applying Math

Math Standards

National: 2, 6, 9

Florida: MA.A.3.4.1, MA.E.1.4.1

Answers to Practice Problems

25. approximately 325 atoms of oxygen, 90 atoms of carbon, and 15 atoms of nitrogen
26. 238.6 g.

Use the graph to answer question 2.

Elements in the Universe

2. What percentage do the elements hydrogen and helium account for in the universe?
- 100 percent
 - 99.9 percent
 - 99.8 percent
 - 98 percent

Use the graph below to answer question 3.

Elements in Earth's Crust

3. Which element makes up 8 percent of Earth's crust?
- aluminum
 - iron
 - oxygen
 - silicon
4. Which element has the physical property of magnetism?
- calcium
 - iron
 - oxygen
 - sodium

SCB.1.4.2

5. Which statement best describes the law of conservation of mass?
- The mass of the products is always greater than the mass of the materials that react in a chemical change.
 - The mass of the products is always less than the mass of the materials that react in a chemical change.
 - A certain mass of material must be present for a reaction to occur.
 - Matter is neither lost nor gained during a chemical change.

Extended Response

11. By definition, a compound is a substance made from two or more elements. All compounds are fixed in the proportions of that compound. If the ratio of the elements changes, then a new compound is formed. Examples are: water, carbon dioxide, salt, and sugar. Accept answers that students may provide as long as they are compounds.
12. The experiment should include these components: Design an enclosure to trap all solid and gas products of the reaction. With the enclosure covering the reactants, measure the total mass (enclosure plus all reactants to be burned.) With enclosure in place, start the reaction. Once burning is complete, measure the total mass again. The initial and final masses will be equal.

Rubrics

For more help evaluating Short- and Extended-Response questions, see the rubrics on p. 10T.

6. The most plentiful element in the universe readily burns in air. What is this chemical property called?

- A. flammability
- B. ductility
- C. density
- D. boiling point

Gridded Response

SC.1.12.2

7. In the following reaction, 24 g of CH_4 (methane) react completely with 96 g of O_2 to form 66 g of CO_2 . How many grams of H_2O are formed?
8. A reaction of 22.85 g of sodium hydroxide (NaOH) with 20.82 g of hydrogen chloride (HCl) gives off 10.29 g of water (H_2O). What mass of sodium chloride (NaCl) is formed in this reaction?

READ

EXPLAIN

Short Response

Use the illustration below to answer questions 9.

9. What physical properties could be used to identify these minerals?

10. You are given a mixture of iron filings, sand, and salt. Describe how to separate this mixture.

READ
INQUIRE
EXPLAIN

Extended Response

SC.1.2.2

11. Describe how a compound is a combination of elements in a fixed proportion. Give two examples.

Use the illustration below to answer question 12.

SC.1.12.2

12. Design an experiment that shows that this type of chemical change is governed by the law of conservation of mass.

Test-Taking Tip

Directions and Instructions Listen carefully to the instructions from your teacher. Read the directions and each question carefully.

Short Response

9. Physical properties of these minerals include color, shape, magnetism, density, melting point, and boiling point.
10. Add water to the mixture. Stir until all the salt is dissolved, then pour the water/salt solution off of the sand/iron mixture. Use a magnet to separate the iron and sand.

Subatomic Collision

© Thompson

Scientists believe atomic is so small that it would take 100 million of them lined up in a row to equal the width of a pin. Atoms, however, can be divided into component parts – and amazingly, some of those parts (tiny particles) that are literally *not* atoms are made up of these subatomic particles called quarks, electrons, and neutrinos.

1. What do you think scientists have just “assembled” discovered these subatomic particles?
2. What might scientists learn by breaking apart atoms, nuclei?

What makes the glass glow?

8 minutes

19

Have you ever seen an incandescent, low-voltage night or marker power? *Incandescent* describes a thin wire, encased in a fluorescent gas container, that creates heat as well as luminous glass. This interesting glass has a variety of green, silver and glow-in-the-dark lighting and effects.

1. What materials are used to make incandescent bulbs?

2. What is the purpose of the glass in the bulb?

3. How does the glass in the bulb create light?

This is a representation of key blackline masters available in the Teacher Classroom Resources. See Resource Manager boxes within the chapter for additional information.

Key to Teaching Strategies

The following designations will help you decide which activities are appropriate for your students.

- L1** Level 1 activities should be appropriate for students with learning difficulties.
- L2** Level 2 activities should be within the ability range of all students.
- L3** Level 3 activities are designed for above-average students.

ELL ELL activities should be within the ability range of English Language Learners.

COOP LEARN Cooperative Learning activities are designed for small group work.

 Multiple Learning Styles logos, as described on page 12T, are used throughout to indicate strategies that address different learning styles.

P These strategies represent student products that can be placed into a best-work portfolio.

PBL Problem-Based Learning activities apply real-world situations to learning.

Properties of Alkali and the Alkaline Table

K-12 Science
19

Direct link: <https://www.ck12.org/properties-of-alkali-and-alkaline-earth-elements/>

Characteristics of Some Alkaline Earth Metals

Element	Atomic number	Mass number	Melting point (°C)	Boiling point (°C)
Magnesium	12	24	936.1	1363
Calcium	20	40	842	1484
Strontium	38	88	770	1384
Barium	56	137	725	1646

1. According to the table, which alkali earth metal has the **HIGHEST** atomic number greater than zero?

a. Magnesium
b. Strontium

c. Calcium
d. Barium
2. According to the table, which element is the **LOWEST** atomic number?

a. Magnesium
b. Strontium

c. Calcium
d. Barium
3. According to the table, which element has the **HIGHEST** melting point?

a. Magnesium
b. Strontium

c. Calcium
d. Barium
4. The number of neutrons in the nucleus of an atom is equal to the mass number minus the atomic number. According to the table, how many neutrons are in the nucleus of a strontium atom?

a. 50
b. 51

c. 52
d. 53

1. Testing Concepts

Directions: Questions 1 through 10 are multiple-choice questions. Select the one alternative that best completes the statement or answers the question.

1. The central core of an atom is called the **_____**.
2. The short distance between the positively charged nucleus and the negatively charged electrons is called the **_____**.
3. The mass of an atom is almost equal to the mass of its **_____**.
4. The **_____** of an atom is the mass assigned to the carbon-12 isotope.
5. The **_____** of an atom is the mass assigned to the carbon-12 isotope.
6. The number of protons in a **_____** is **_____**.
7. The number of protons in a **_____** is **_____**.
8. An isotope of carbon has 6 protons and 12 nucleons. It has 6 neutrons and 6 electrons.

9. Neutron number is **_____** of an element's atomic mass and **_____** of an element's atomic number.
10. Neutron number is **_____** of an element's atomic mass and **_____** of an element's atomic number.
11. The mass of an electron is **_____** of the mass of a proton.
12. The mass of an electron is **_____** of the mass of a proton.
13. The mass of an electron is **_____** of the mass of a proton.
14. The mass of an electron is **_____** of the mass of a proton.
15. The mass of an electron is **_____** of the mass of a proton.
16. The mass of an electron is **_____** of the mass of a proton.
17. The mass of an electron is **_____** of the mass of a proton.
18. The mass of an electron is **_____** of the mass of a proton.
19. The mass of an electron is **_____** of the mass of a proton.
20. The mass of an electron is **_____** of the mass of a proton.

Science Content Background

Structure of the Atom

Models—Tools for Scientists

In 1926, Austrian physicist Erwin Schrodinger (1887–1961) proposed the quantum mechanical model of the atom. The model was based on the wavelike properties of the electron. Electrons were no longer seen as small particles moving around the nucleus in a defined path. In fact, it was shown

in 1927 by Werner Heisenberg (1901–1976), described in the Heisenberg Uncertainty Principle, that it is impossible to know precisely both an electron's position and momentum at a given time. Since that time, the location of electrons in an atom has been described as an electron cloud. An electron cloud is a volume of space where an electron with a certain amount of energy is most likely to be found.

Teacher to Teacher

Petrolia Moss, Teacher
North Heights Junior High
Texarkana, AR

"Multicolored modeling clay is an inexpensive and reusable material for middle school students to use to visualize science concepts. Students use their creativity to make 'atoms' that have touchable protons, neutrons, and electrons."

Petrolia Moss

Masses of Atoms

Isotopes

Isotopes are atoms of the same element with different numbers of neutrons. Many isotopes, such as carbon-14, occur naturally, and scientists have succeeded in producing many artificial isotopes. Isotopes that are radioactive are called radioisotopes. Among other applications, radioisotopes are used as tracers in medicine, geology, and biology research and are used to measure the thickness of materials in industry.

section The Periodic Table

Organizing the Elements

In 1817, the German chemist Johann Dobereiner found that he could arrange many elements into groups that he called triads. He noticed for example that lithium, sodium, and potassium react vigorously with water. Similar regularities were uncovered for calcium, strontium, and barium, and for fluorine, chlorine, and bromine.

Dobereiner's early work laid the groundwork for other chemists as they searched for an organizing principle by which to classify elements. In 1863, English chemist John Newlands proposed that when the known elements were arranged according to atomic mass, similarities in chemical properties occurred with every eighth element. He called this regularity the law of octaves. This regularity was also noticed by Dmitri Mendeleev. Mendeleev arranged the elements into a periodic table, which he published in 1869.

The modern periodic table didn't come into being until a Dutch physicist, Anton van den Broek, proposed that the elements should be arranged according to nuclear charge rather than atomic mass. Henry Mosely confirmed this hypothesis through studies of the X-ray spectra of a series of elements that had consecutive positions on the table. The change to ordering by atomic number resulted in the reversal of the positions of a few elements.

The Atom and the Periodic Table

The period in which an element appears in the periodic table indicates how many main electron energy levels that are in that atom. For example, oxygen is in the second period, so the oxygen atom has two main energy levels. The group number (for main group elements) indicates how many electrons are in the outermost

energy level. Oxygen has six outer or valence electrons, so oxygen is in Group 6A. It is these outermost electrons that determine how an atom reacts.

For every principle quantum number (period or horizontal row), there are sublevels designated by letters, such as *s*, *p*, *d*, and *f*. In the sublevels, electron pairs are found in orbitals. There is a maximum of one *s* orbital, three *p* orbitals, five *d* orbitals, and seven *f* orbitals in an energy level. As you move across any period of the table, Groups 1 and 2 are filling *s* orbitals with two electrons. Groups 13–18 are filling *p* orbitals with six electrons. In periods 4 through 7, the transition elements, Groups 3–10, are filling five *d* orbitals with ten electrons. The inner transition elements, located below the periodic table, are filling the *4f* and *5f* orbitals with 14 electrons.

Atoms Compose All Things, Great and Small

Everything in this photo and the universe is composed of tiny particles called atoms. You will learn about atoms and their components: protons, neutrons, electrons, and quarks.

Science Journal In your Science Journal, write a few paragraphs about what you know about atoms.

Theme Connection

Scale and Structure The underlying small-scale structure of atoms determines the properties of elements and their positions on the periodic table of elements.

About the Photo

Atoms It is important for students to understand that all things are composed of atoms. Some students may not realize that even substances found in space are composed of atoms. In fact, stars like the Sun produce energy through the fusion of hydrogen to helium. Heavier elements are formed through fusion processes too.

Start-Up Activities

Inferring What You Can't Observe

How do detectives solve a crime when no witnesses saw it happen? How do scientists study atoms when they cannot see them? In situations such as these, techniques must be developed to find clues to answer questions. Do the lab below to see how clues might be gathered.

1. Take an envelope and several items from your teacher.
2. Place an assortment of items in the envelope and seal it.
3. Trade envelopes with another group.
4. Without opening the envelope, try to figure out the types and number of items that are in the envelope. Record a hypothesis about the contents of the envelope in your Science Journal.
5. After you record your hypothesis, open the envelope and see what is inside.
6. **Think Critically** Describe the contents of your envelope. Was your hypothesis correct?

FOLDABLES™ Study Organizer

Atoms You have probably studied atoms before. Make the following Foldable to help identify what you already know, what you want to know, and what you learn about atoms.

STEP 1 Fold a sheet of paper vertically from side to side. Make the front edge about 1.25 cm shorter than the back edge.

STEP 2 Turn lengthwise and fold into thirds.

STEP 3 Unfold and cut only the top layer along both folds to make three tabs.

STEP 4 Label each tab as shown.

Identify Questions Before you read the chapter, write what you already know about atoms under the left tab of your Foldable, and write questions about what you'd like to know under the center tab. After you read the chapter, list what you learned under the right tab.

Video Lab available for this Lab.

Purpose Use the Launch Lab to show students how to use inference to describe something they cannot see. **L2** **KS** **Kinesthetic**

Preparation Obtain several items, such as chalk, eraser, thimble, bottle cap, or washer.

Materials envelopes, chalk, eraser, thimble, bottle cap, washer.

Teaching Strategy Suggest that students:

- lay a piece of thin paper over the sealed envelope and rub the side of a pencil over the items.
- hold the envelope up to a bright light to see an outline of the items.
- shake the envelope from side to side to see whether the items are flat or round.

Think Critically

Answers will vary depending on the assortment of items. The clues students find should be used in their conclusions.

Assessment

Oral Ask students whether they have ever attempted to guess the contents of a wrapped gift. Have them explain how they used inference to get clues. Finally, ask them to explain how their gift-guessing might be similar to the reasoning used by atomic scientists to determine atomic structure. Use **Performance Assessment in the Science Classroom**, p. 89.

Section Focus Transparency Subatomic Collision Chapter 19

An individual atom is so small that it would take 50 million of them lined up in a row to equal one centimeter! Atoms, however, can be divided into component parts and, amazingly, some of these parts have particles that are tinier yet. Below is an image created by these subatomic particles taken by a device called a bubble chamber.

1. Why do you think scientists have only recently discovered these subatomic particles?

2. What might scientists learn by breaking apart atomic nuclei?

Properties of Matter and the Periodic Table

Reading Preview

Tie to Prior Knowledge

Brainstorm Names Have students brainstorm a list of the names of elements that they know without referring to a periodic table. Record the list on the board or on chart paper. Make sure that things like brass or steel, which are mixtures of elements, are not accepted. L2

Activate Vocabulary Knowledge

Ask students to discuss with a partner the following question: What is the smallest piece of matter that makes up an element? **Atom** Point out **Figure 6**, the most current atomic model. Have them locate the vocabulary words in **Figure 6** and predict where the other words may fit.

Reading Guide

What You'll Learn

- **Identify** the names and symbols of common elements.
- **Identify** quarks as subatomic particles of matter.
- **Describe** the electron cloud model of the atom.
- **Explain** how electrons are arranged in an atom.

Why It's Important

Everything that you see, touch, and breathe is composed of tiny atoms.

Review Vocabulary

element: substance with atoms that are all alike

New Vocabulary

- atom
- nucleus
- proton
- neutron
- electron
- quark
- electron cloud

Scientific Shorthand

Do you have a nickname? Do you use abbreviations for long words or the names of states? Scientists also do this. In fact, scientists have developed their own shorthand for dealing with long, complicated names.

Do the letters C, Al, Ne, and Ag mean anything to you? Each letter or pair of letters is a chemical symbol, which is a short or abbreviated way to write the name of an element. Chemical symbols, such as those in **Table 1**, consist of one capital letter or a capital letter plus one or two lowercase letters. For some elements, the symbol is the first letter of the element's name. For other elements, the symbol is the first letter of the name plus another letter from its name. Some symbols are derived from Latin. For instance, *argentum* is Latin for "silver." Elements have been named in a variety of ways. Some elements are named to honor scientists, for places, or for their properties. Other elements are named using rules established by an international committee. Regardless of the origin of the names, scientists derived this international system for convenience. It is much easier to write H for hydrogen, O for oxygen, and H₂O for dihydrogen oxide (water) than to write out the names. Because scientists worldwide use this system, everyone understands what the symbols mean.

Table 1 Symbols of Some Elements

Element	Symbol	Element	Symbol
Aluminum	Al	Iron	Fe
Calcium	Ca	Mercury	Hg
Carbon	C	Nitrogen	N
Chlorine	Cl	Oxygen	O
Gold	Au	Potassium	K
Hydrogen	H	Sodium	Na

Atomic Components

An element is matter that is composed of one type of **atom**, which is the smallest piece of matter that still retains the property of the element. For example, the element silver is composed of only silver atoms, and the element hydrogen is composed of only hydrogen atoms. Atoms are composed of particles called protons, neutrons, and electrons, as shown in **Figure 1**. Protons and neutrons are found in a small, positively-charged center of the atom called the **nucleus**, which is surrounded by a cloud containing electrons. **Protons** are particles with an electrical charge of $1+$. **Neutrons** are neutral particles that do not have an electrical charge. **Electrons** are particles with an electrical charge of $1-$. Atoms of different elements differ in the number of protons they contain.

Reading Check What are the particles that make up the atom and where are they located?

Quarks: Even Smaller Particles

Are the protons, electrons, and neutrons that make up atoms the smallest particles that exist? Scientists hypothesize that electrons are not composed of smaller particles and are one of the most basic types of particles. Protons and neutrons, however, are made up of smaller particles called **quarks**. So far, scientists have confirmed the existence of six uniquely different quarks. Scientists theorize that an arrangement of three quarks held together with the strong nuclear force produces a proton. Another arrangement of three quarks produces a neutron. The search for the composition of protons and neutrons is an ongoing effort.

Figure 1 The nucleus of the atom contains protons and neutrons that are composed of quarks. The proton has a positive charge and the neutron has no charge. A cloud of negatively charged electrons surrounds the nucleus of the atom.

Explain how atoms of different elements differ.

Science Online

Topic: Particle Research

Visit fl.gpscience.com for Web links to information about particle research at Fermi National Accelerator Laboratory.

Activity Write a paragraph describing the information that you found at the site.

2 Teach

Caption Answer

Figure 1 by the number of protons they contain

Use Science Words

Word Usage Have students compare and contrast the use of the word *nucleus* in biology and in physical science. In biology, *nucleus* refers to the cellular organelle where control of cell functions originates. It is in the interior of the cell, but not necessarily at the center. In physical science, the nucleus is also a sort of control area because the number of protons found in the nucleus determines the identity of the atom. The nucleus of an atom, however, is located at the center of the atom.

L2 **IS** Linguistic

Reading Check

Answer Particles that make up atoms include protons and neutrons, which are located in the nucleus, and electrons, which are located in a cloud surrounding the nucleus.

Make a Model

Nesting Dolls Obtain a set of nesting dolls and place them in the front of the room. Ask students what they think is inside. After they respond, open the largest figure and reveal the smaller one. Continue this until you reach the last doll. How are the dolls similar to the search for smaller nuclear particles? Scientists thought several times that they had found the smallest particles, but each time they found even smaller particles. Now scientists would say that the last doll is like a quark. **L2**

IS Visual-Spatial

Reading Strategy

Illustrations As they read, have students write their own definitions of the vocabulary words based on the information found in the text. Ask them to begin a drawing of an atom using **Figure 6** as a starting point. Tell them to add more detail as they read. Ask them to label all the parts using the vocabulary words.

Differentiated Instruction

English-Language Learners Have students use colored pencils to draw a diagram of an atom of the element lithium. Students should draw the correct numbers of protons, neutrons, and electrons. Students should color code the components and provide a key to their diagram. Have students use 3 protons, 4 neutrons, and 3 electrons in their diagram. **L2** **ELL**

Discussion

Quarks Why are scientists having trouble determining the composition of protons and neutrons? Until recently, technology was not available to determine the existence of quarks. Subatomic particles are difficult to study because of their size.

Use an Analogy

Snow Tracks People walking in snow or skiing down a mountain leave their tracks behind. If there were no snow, tracks of activity would be much more difficult to see. When detecting quarks or other atomic particles, scientists create an environment that helps them see the tracks the moving particles leave behind. In a cloud chamber, a dense cloud condenses to an even denser track when a particle passes through. Just as skiers leave a different track than do snowboarders, an electron moving through the dense cloud leaves a different track than does a proton. L2

Caption Answer

Figure 2 to accelerate the particles so they will have enough energy to break each other apart when they collide

Quick Demo Gathering Evidence

Materials one large sheet of poster board, various types of markers and pens, tape, magnifying lens

Estimated Time 10 minutes

Procedure Display a large poster in front of the class on which you have made several curved lines using different markers and pens. Tape the markers and pens to the poster board and provide a magnifying lens. Ask students to match the pen with the appropriate line by examining the pen tip with the lens. Next, ask what other method they could use to identify the lines. **Make comparison marks with each pen or marker.** Tell students that nuclear scientists use both predictions and matching techniques.

Figure 2 The Tevatron is a huge machine. The aerial photograph of Fermi National Accelerator Laboratory shows the circular outline of the Tevatron particle accelerator. The close-up photograph of the Tevatron gives you a better view of the tunnel.

Infer Why is such a long tunnel needed?

Finding Quarks To study quarks, scientists accelerate charged particles to tremendous speeds and then force them to collide with—or smash into—protons. This collision causes the proton to break apart. The Fermi National Accelerator Laboratory, a research laboratory in Batavia, Illinois, houses a machine that can generate the forces that are required to make protons collide. This machine, the Tevatron, shown in **Figure 2**, is approximately 6.4 km in circumference. Electric and magnetic fields are used to accelerate, focus, and make the fast-moving particles collide.

The particles that result from the collision can be detected by various collection devices. Often, scientists use multiple collection devices to collect the greatest possible amount of information about the particles created in a collision. Just as police investigators can reconstruct traffic accidents from tire marks and other clues at the scene, scientists are able to examine and gather information about the particles, as shown in **Figure 3**. Scientists use inferences to identify the subatomic particles and to discover information about each particle's inner structure.

The Sixth Quark Finding evidence for the existence of quarks was not an easy task. Scientists found five quarks and hypothesized that a sixth quark existed. However, it took a team of nearly 450 scientists from around the world several years to find the sixth quark. The tracks of the sixth quark were hard to detect because only about one-billionth of a percent of the proton collisions performed showed the presence of a sixth quark, typically referred to as the *top* quark.

Teacher FYI

Cloud Chambers The first cloud chambers were developed near the beginning of the 1900s by C.T.R. Wilson, a Scottish physicist. He was trying to reproduce weather conditions in a closed chamber. Supersaturated vapor formed in the chamber and formed

visible vapor trails when X rays passed through. This led to more sophisticated bubble chambers for detailed study of the vapor trails formed as beta and alpha particles passed through the supersaturated vapor.

Models—Tools for Scientists

Scientists and engineers use models to represent things that are difficult to visualize or picture in the mind. You might have seen models of buildings, the solar system, or airplanes. These are scaled-down models. Scaled-down models allow you to see either something too large to see all at once or something that has not been built yet. Scaled-up models are often used to visualize things that are too small to see. To give you an idea of how small the atom is, it would take about 24,400 atoms stacked one on top of the other to equal the thickness of a sheet of aluminum foil. To study the atom, scientists have developed scaled-up models that they can use to visualize how the atom is constructed. For the model to be useful, it must support all of the information that is known about matter and the behavior of atoms. As more information about the atom is collected, scientists change their models to include the new information.

 **Reading Check** Explain how models can simplify science.

The Changing Atomic Model You know now that all matter is composed of atoms, but this was not always known. Around 400 B.C., Democritus proposed the idea that atoms make up all substances. However, another famous Greek philosopher, Aristotle, disputed Democritus's theory and proposed that matter is uniform throughout and is not composed of smaller particles. Aristotle's incorrect theory was accepted for about 2000 years. In the 1800s, John Dalton, an English scientist, was able to offer proof that atoms exist.

Dalton's model of the atom, a solid sphere shown in **Figure 4**, was an early model of the atom. As you can see in **Figure 5**, the model has changed somewhat over time. Dalton's modernization of Aristotle's idea of the atom provided a physical explanation for chemical reactions. Scientists could then express these reactions in quantitative terms using chemical symbols and equations.

Figure 4 John Dalton's atomic model was a simple sphere.

SECTION 1 Structure of the Atom 581

Differentiated Instruction

Challenge Have students research models that are used in other fields such as architecture, aerospace, or the automotive industry. Have students bring in a model of their choice and make a presentation to the class on how the models are used by scientists and engineers in their selected field. **L3**

Visual Learning

Figure 4 Tell students that the wooden sphere atom models that Dalton constructed are on display in the Science Museum in London. Many of his contemporaries ridiculed his idea of atoms simply on the basis that atoms could not be seen and, therefore, did not exist. What are some other things that exist but can't be seen? **Possible answers:** electromagnetic waves, air **L2**  **Visual-Spatial**

Mini LAB

Modeling an Aluminum Atom

Procedure

1. Arrange thirteen 3-cm circles cut from **orange paper** and fourteen 3-cm circles cut from **blue paper** on a **flat surface** to represent the nucleus of an atom. Each orange circle represents one proton, and each blue circle represents one neutron.
2. Position two holes punched from **red paper** about 20 cm from your nucleus.
3. Position eight punched holes about 40 cm from your nucleus.
4. Position three punched holes about 60 cm from your nucleus.

Analysis

1. How many protons, neutrons, and electrons does an aluminum atom have?
2. Explain how your circles model an aluminum atom.
3. Explain why your model does not accurately represent the true size and distances in an aluminum atom.

Mini LAB

Purpose to make a model showing the particles in an atom **L2**

Materials blue, orange, and red paper, metric ruler, hole punch

Teaching Strategy To save time, prepare the circles and the punched holes ahead of time.

Analysis

1. 13 protons, 14 neutrons, and 13 electrons
2. Like an aluminum atom, the model has 13 protons and 14 neutrons. It also has three energy levels with 2 electrons in the first level, 8 in the second, and 3 in the third.
3. In reality, protons and neutrons are more than 1,800 times larger than electrons. This activity does not attempt to model subatomic particle radii nor their exact locations in the cloud. It is merely modeling the grouping that occurs within the cloud.

Assessment

Process Have students use their materials to make models of atoms of as many different elements as they can. Ask them to make lists of the atoms they made, and draw a quick sketch of each one. Use **Performance Assessment in the Science Classroom**, p. 97.

Reading Check

Answer Models are less expensive to build than the actual item and they allow the study of things that are difficult to visualize or duplicate.

Visualizing The Atomic Model

Have students examine the pictures and read the captions. Then ask the following questions.

What significant changes occurred in the atomic model between **Figure 5A** and **Figure 5B**? Scientists found that the atom was not "uncuttable" but was composed of positive and negative particles.

What significant changes occurred in the atomic model between **Figure 5B** and **Figure 5C**? Scientists found that the mass of the atom was concentrated in the center instead of throughout the atom and that electrons orbit the nucleus.

What significant changes occurred in the atomic model between **Figure 5C** and **Figure 5D**? Scientists found that the orbits of the electrons are not random but are at fixed distances from the nucleus. Scientists also found that the nucleus is composed of protons and neutrons.

Activity

Rutherford Report Have students research and find out how Rutherford discovered that the mass of the atom is concentrated primarily in the center of the atom. Ask students to write brief reports in their Science Journals describing Rutherford's experiment. **L2** **IS** **Linguistic**

Figure 5

The ancient Greek philosopher Democritus proposed that elements consist of tiny, solid particles that cannot be subdivided (**A**). He called these particles *atomos*, meaning "uncuttable." This concept of the atom's structure remained largely unchallenged until the 1900s, when researchers began to discover through experiments that atoms are composed of still smaller particles. In the early 1900s, a number of models for atomic structure were proposed (**B-D**). The currently accepted model (**E**) evolved from these ideas and the work of many other scientists.

A DEMOCRITUS'S UNCUTTABLE ATOM

B **THOMSON MODEL, 1904** English physicist Joseph John Thomson inferred from his experiments that atoms contain small, negatively charged particles. He thought these "electrons" (in red) were evenly embedded throughout a positively charged sphere, much like chocolate chips in a ball of cookie dough.

C **RUTHERFORD MODEL, 1911** Another British physicist, Ernest Rutherford, proposed that almost all the mass of an atom—and all its positive charges—is concentrated in a central atomic nucleus surrounded by electrons.

D **BOHR MODEL, 1913** Danish physicist Niels Bohr hypothesized that electrons travel in fixed orbits around the atom's nucleus. James Chadwick, a student of Rutherford, concluded that the nucleus contains positive protons and neutral neutrons.

E **ELECTRON CLOUD MODEL, CURRENT** According to the currently accepted model of atomic structure, electrons do not follow fixed orbits but tend to occur more frequently in certain areas around the nucleus at any given time.

The Electron Cloud Model By 1926, scientists had developed the electron cloud model of the atom that is in use today. An **electron cloud** is the area around the nucleus of an atom where its electrons are most likely found. The electron cloud is 100,000 times larger than the diameter of the nucleus. In contrast, each electron in the cloud is much smaller than a single proton.

Because an electron's mass is small and the electron is moving so quickly around the nucleus, it is impossible to describe its exact location in an atom. Picture the spokes on a moving bicycle wheel. They are moving so quickly that you can't pinpoint any single spoke. All you see is a blur that contains all of the spokes somewhere within it. In the same way, an electron cloud is a blur containing all of the electrons of the atom somewhere within it. **Figure 6** illustrates what the electron cloud might look like.

Figure 6 The electrons are located in an electron cloud surrounding the nucleus of the atom.

Post Reading

Metacognition Working in groups, have students devise a metacognitive method to help them remember and more fully understand the charges and locations of the subatomic particles neutron, proton, and electron. Have groups report any analogies, word associations, or study strategies they created to remember the terms and the structure of an atom.

3 Assess

DAILY INTERVENTION

Check for Understanding

Linguistic Have students write a narrative describing the changes in the atomic model through time. **L2 P**

Reteach

Demonstrating Atoms Place some sesame seeds inside a balloon and carefully (do not breathe in any seeds) inflate and tie off the balloon. As you shake the balloon, ask students how this model could represent electrons in an atom. *The seeds are small compared to the balloon, they are constantly moving, their locations are difficult to predict.* Ask students how this model does not parallel the electrons in an atom. *The balloon has a specific boundary beyond which the seeds cannot move. Electrons can move away from atoms.* **L2 LS Visual-Spatial**

section 1 review

Summary

Scientific Shorthand

- Scientists use chemical symbols as shorthand when writing the names of elements.

Atomic Components

- Atoms are composed of small particles that have known charges.
- Atoms of different elements differ in the number of protons they contain.

Quarks: Even Smaller Particles

- So far, scientists have confirmed the existence of six different quarks.

Models: Tools for Scientists

- Models are used by scientists to simplify the study of concepts and things.
- The current atomic model is an accumulation of over 200 years of knowledge.
- The electron cloud model is the current atomic model.

Self Check

- List** the chemical symbols for the elements carbon, aluminum, hydrogen, oxygen, and sodium.
- Identify** the names, charges, and locations of three kinds of particles that make up an atom.
- Identify** the smallest particle of matter. How were these particles discovered?
- Describe** the electron cloud model of the atom.
- Think Critically** Explain how a rotating electric fan might be used to model the atom. Explain how the rotating fan is unlike an atom.

Applying Math

- Use Numbers** The mass of a proton is estimated to be 1.6726×10^{-24} g, and the mass of an electron is estimated to be 9.1093×10^{-28} g. How many times larger is the mass of a proton than the mass of an electron?
- Calculate** What is the difference between the mass of a proton and the mass of an electron?

section 1 review

- C; Al; H; O; Na
- proton, +1, nucleus; neutron, 0, nucleus; electron, -1, electron cloud
- quark; by accelerating protons and making them collide with so much force that they broke apart
- This model says electrons are most

likely to be found in a cloud surrounding the nucleus; it is 100,000 times larger than the diameter of the nucleus.

- The blades on a rotating fan appear as a smooth metal surface around the center hub. The probability area

for electrons in an atom also presents a solid appearance. The fan blades are different from electrons because they are much larger and, when the fan stops, can easily be seen.

- 1,836 times larger
- 1.6717×10^{-24}

Assessment

Oral Tell students that a fundamental particle is one that cannot be divided into other particles. Ask whether protons, neutrons, or electrons are fundamental particles. *Electrons are fundamental particles. Protons and neutrons are not.* Use **Performance Assessment in the Science Classroom**, p. 89. **L2**

What You'll Learn

- Compute** the atomic mass and mass number of an atom.
- Identify** the components of isotopes.
- Interpret** the average atomic mass of an element.

Why It's Important

Some elements naturally exist in more than one form—radioactive and nonradioactive.

Review Vocabulary

mass: amount of matter in an object

New Vocabulary

- atomic number**
- mass number**
- isotope**
- average atomic mass

Atomic Mass

The nucleus contains most of the mass of an atom because protons and neutrons are far more massive than electrons. The mass of a proton is about the same as that of a neutron—approximately 1.6726×10^{-24} g, as shown in **Table 2**. The mass of each is approximately 1,836 times greater than the mass of an electron. An electron's mass is so small that it is considered negligible when finding the mass of an atom.

If you were asked to estimate the height of your school building, you probably wouldn't give an answer in kilometers. The number would be too cumbersome to use. Considering the scale of the building, you would more likely give the height in a smaller unit, meters. When thinking about the small masses of atoms, scientists found that even grams were not small enough to use for measurement. Scientists need a unit that results in more manageable numbers. The unit of measurement used for atomic particles is the atomic mass unit (amu). The mass of a proton or a neutron is almost equal to 1 amu. This is not coincidence: the unit was defined that way. The atomic mass unit is defined as one-twelfth the mass of a carbon atom containing six protons and six neutrons. Remember that the mass of the carbon atom is contained almost entirely in the mass of the protons and neutrons that are located in the nucleus. Therefore, each of the 12 particles in the nucleus must have a mass nearly equal to 1 amu.

Reading Check

Where is the majority of the mass of an atom located?

Table 2 Subatomic Particle Masses

Particle	Mass (g)
Proton	1.6726×10^{-24}
Neutron	1.6749×10^{-24}
Electron	9.1093×10^{-28}

Table 3 Mass Numbers of Some Atoms

Element	Symbol	Atomic Number	Protons	Neutrons	Mass Number	Average Atomic Mass*
Boron	B	5	5	6	11	10.81 amu
Carbon	C	6	6	6	12	12.01 amu
Oxygen	O	8	8	8	16	16.00 amu
Sodium	Na	11	11	12	23	22.99 amu
Copper	Cu	29	29	34	63	63.55 amu

*The atomic mass units are rounded to two decimal places.

Protons Identify an Element You learned earlier that atoms of different elements are different because they have different numbers of protons. In fact, the number of protons tells you what type of atom you have and vice versa. For example, every carbon atom has six protons. Also, all atoms with six protons are carbon atoms. Atoms with eight protons are oxygen atoms. The number of protons in an atom is equal to a number called the **atomic number**. The atomic number of carbon is 6. Therefore, if you are given any one of the following—the name of the element, the number of protons in the element, or the atomic number of the element—you can determine the other two.

 **Reading Check** Which element is an atom with six protons in the nucleus?

Mass Number The **mass number** of an atom is the sum of the number of protons and the number of neutrons in the nucleus of the atom. Look at **Table 3** to see that this is true.

If you know the mass number and the atomic number of an atom, you can calculate the number of neutrons. The number of neutrons is equal to the atomic number subtracted from the mass number.

$$\text{number of neutrons} = \text{mass number} - \text{atomic number}$$

Atoms of the same element with different numbers of neutrons can have different properties. For example, carbon with a mass number equal to 12, or carbon-12, is the most common form of carbon. Carbon-14 is present on Earth in much smaller quantities. Carbon-14 is radioactive, while carbon-12 is not.

Teacher FYI

Isotopes Nearly all elements have isotopes, some of which are radioactive. The mass of an element listed on the periodic table is the weighted average of the masses of the isotopes of that element.

Differentiated Instruction

Visually Impaired If **Table 3** is difficult for some to read, use one type of object, such as small corks, to represent protons and another type, such as rubber stoppers, to represent neutrons. Have students assemble the right numbers of protons and neutrons for the atoms listed in **Table 3**. L2

2 Teach

Reading Check

Answer in the nucleus

Answer carbon

Discussion

Atom Charge How many electrons are found in a neutral atom of carbon? **six** What would the charge be on the carbon atom if it lost four electrons? Explain. **+ 4; The atom now has 4 more protons than electrons.** How does neutron count affect atomic charge? **It has no effect.** L2

Quick Demo Modeling Atoms

Materials modeling clay (three different colors)

Estimated Time 20 minutes

Procedure Create models of the atoms in **Table 3** using three different colors of modeling clay. Use small balls from two of the colors to create the protons and neutrons in the nucleus. Use the third color to represent the electrons.

Discussion

Atom Numbers Have students determine the number of neutrons, protons, and electrons in neon —20, potassium —39, and gold —197. **Ne: 10 protons, 10 neutrons, 10 electrons; K: 19 protons, 20 neutrons, 19 electrons; Au: 79 protons, 118 neutrons, 79 electrons** L3

 **Logical-Mathematical**

Activity

Element Game Have students play the element game in pairs. One student should write down the name of an element on a piece of paper. This student gives the other student a hint about the name of the element. The student keeps giving hints until the other student guesses the element. L2

IDENTIFYING Misconceptions

Protons v. Neutrons Students may think that since many of the lighter elements have the same number of protons as neutrons, all elements have this property. Remind them that this is not true. Large atoms have more neutrons than protons because neutrons play a role in stabilizing the repulsive forces between the protons in the nucleus.

Carbon Dating Archaeologists are most interested in carbon-13 and carbon-14 because these isotopes are radioactive. The longer a once-living organism has been dead, the less radioactive it will be per gram of carbon. This gives archaeologists a way to determine the approximate age of once-living organisms.

Reading Check

Answer 146 neutrons

Applying Science

Answers

- 48,800 million years;
97,600 million years
- 8,920 million years; lead-206

Reading Strategy

Clarify Text Have students read the text about Atomic Mass. Ask: Are any of the concepts unclear? Write student concerns or misconceptions on the board. Model ways of clarifying the text, such as referring to Table 3 and using supporting facts. Encourage students who understand the concepts to explain them in their own words.

Carbon Dating Living organisms on Earth contain carbon. Carbon-12 makes up 99 percent of this carbon. Carbon-13 and carbon-14 make up the other one percent. Which isotopes are archaeologists most interested in when they determine the age of carbon-containing remains? Explain your answer in your Science Journal.

Isotopes

Not all the atoms of an element have the same number of neutrons. Atoms of the same element that have different numbers of neutrons are called **isotopes**. Suppose you have a sample of the element boron. Naturally occurring atoms of boron have mass numbers of 10 or 11. How many neutrons are in a boron atom? It depends upon the isotope of boron to which you are referring. Obtain the number of protons in boron from the periodic table. Then use the formula on the previous page to calculate the number of neutrons in each boron isotope. You can determine that boron can have five or six neutrons.

Reading Check

Uranium-238 has 92 protons. How many neutrons does it have?

Applying Science

How can radioactive isotopes help tell time?

Atoms can be used to measure the age of bones or rock formations that are millions of years old. The time it takes for half of the radioactive atoms in a piece of rock or bone to change into another element is called its half-life. Scientists use the half-lives of radioactive isotopes to measure geologic time.

Half-Lives of Radioactive Isotopes

Radioactive Element	Changes to This Element	Half-Life
Uranium-238	lead-206	4,460 million years
Potassium-40	argon-40, calcium-40	1,260 million years
Rubidium-87	strontium-87	48,800 million years
Carbon-14	nitrogen-14	5,715 years

Identifying the Problem

The table above lists the half-lives of some radioactive isotopes and into which elements they change. For example, it would take 5,715 years for half of the carbon-14 atoms in a rock to change into atoms of nitrogen-14. After another 5,715 years, half of the remaining carbon-14 atoms will change, and so on. You can use these radioactive clocks to measure different periods of time.

Solving the Problem

- How many years would it take half of the rubidium-87 atoms in a piece of rock to change into strontium-87? How many years would it take for 75 percent of the atoms to change?
- After a long period, only 25 percent of the atoms in a rock remained uranium-238. How many years old would you predict the rock to be? The other 75 percent of the atoms are now which radioactive element?

Visual Learning

Figure 7 Have students draw diagrams in their Science Journals of the nuclei of carbon-12, carbon-13, and carbon-14. **Carbon-12 has 6 protons and 6 neutrons, carbon-13 has 6 protons and 7 neutrons, and carbon-14 has 6 protons and 8 neutrons.** [L2] [L3] **Visual-Spatial**

Differentiated Instruction

Challenge Have students research radioactive isotopes that are used in medicine. Have students give a presentation to the class about the types of isotopes used and what they are used for. [L3]

Identifying Isotopes Models of two isotopes of boron are shown in **Figure 7**. Because the numbers of neutrons in the isotopes are different, the mass numbers are also different. You use the name of the element followed by the mass number of the isotope to identify each isotope: boron-10 and boron-11. Because most elements have more than one isotope, each element has an average atomic mass. The **average atomic mass** of an element is the weighted-average mass of the mixture of its isotopes. For example, four out of five atoms of boron are boron-11, and one out of five is boron-10. To find the weighted-average, or the average atomic mass of boron, you would use the following equation:

$$\frac{4}{5}(11 \text{ amu}) + \frac{1}{5}(10 \text{ amu}) = 10.8 \text{ amu}$$

The average atomic mass of the element boron is 10.8 amu. Note that the average atomic mass of boron is close to the mass of its most abundant isotope, boron-11.

Figure 7 Boron-10 and boron-11 are two isotopes of boron. These two isotopes differ by one neutron.

Explain why these atoms are isotopes.

Post Reading

Ask Questions Have students review the list of questions generated during the SQ3R activity. Now that students have read about atomic mass and isotopes, have volunteers provide answers to the questions. Ask if students have new questions.

Caption Answer

Figure 7 These atoms are isotopes because they have the same number of protons, but differ in the number of neutrons.

3 Assess

DAILY INTERVENTION

Check for Understanding

Visual-Spatial Have students use colored pencils to draw the electron cloud model for lithium. Students should include the correct number of protons and electrons. Tell students to include four neutrons in their drawing. **L2 P**

Reteach

Weighted Averages Have students calculate the weighted average of student quiz scores if the following results were obtained: 5 students scored 80%; 19 students scored 90%.

$$\left(\frac{5}{24} \times 80\right) + \left(\frac{19}{24} \times 90\right) = 88$$

L2 IN Logical-Mathematical

Assessment

Oral Place a small plastic container on a table. Have students count as you place colored marbles, representing protons, into the bowl. When you stop, ask them to identify the element. Then ask them to predict the number of neutrons needed for a particular isotope of that element. Use PASC, p. 89. **L2**

section 2 review

Summary

Atomic Mass

- The nucleus contains most of the mass of an atom.
- The masses of a proton and neutron are approximately equal.
- The mass of an electron is considered negligible when finding the mass of an atom.
- The unit of measurement for atomic particles is the atomic mass unit (amu).
- The carbon-12 isotope was used to define the atomic mass unit.
- The number of protons identifies an element.

Isotopes

- Atoms of the same element with different numbers of neutrons are called isotopes.
- The average atomic mass of an element is the weighted-average mass of the mixture of isotopes.

Self Check

1. **Identify** the mass number and atomic number of a chlorine atom that has 17 protons and 18 neutrons.
2. **Explain** how the isotopes of an element are alike and how are they different.
3. **Explain** why the atomic mass of an element is an average mass.
4. **Explain** how you would calculate the number of neutrons in potassium-40.
5. **Think Critically** Chlorine has an average atomic mass of 35.45 amu. The two naturally occurring isotopes of chlorine are chlorine-35 and chlorine-37. Why does this indicate that most chlorine atoms contain 18 neutrons?

Applying Math

6. **Use Numbers** If a hydrogen atom has two neutrons and one proton, what is its mass number?
7. **Use Tables** Use the information in Table 2 to find the mass in kilograms of each subatomic particle.

section 2 review

1. Mass number = 35; atomic number = 17
2. Isotopes have the same number of protons but different numbers of neutrons.
3. Elements have several isotopes with different numbers of neutrons, and thus different masses. The average atomic mass is the weighted average of the masses of the element's isotopes.
4. Mass number — atomic number = number of neutrons = 40 — 19 = 21
5. The average of 35.45 lies closer to the 35 mass number than to the 37 mass number.
6. 3
7. proton = 1.6726×10^{-27} kg
neutron = 1.6749×10^{-27} kg
electron = 9.1093×10^{-31} kg

Repeating Patterns Students are already familiar with the repeating pattern of the days of the week. Point out that just as a calendar illustrates the periodic pattern of the days of the week, the periodic table illustrates the periodic patterns of the chemical properties of chemical elements. L2

Facets of Meaning Ask students why their class sessions are called periods. Tell them *Periodical* is a name for a magazine that is published weekly or at regular intervals. Then tell them they will learn about a similar pattern that led to the table of elements being named the periodic table.

Reading Guide

What You'll Learn

- Explain** the composition of the periodic table.
- Use** the periodic table to obtain information.
- Explain** what the terms *metal*, *nonmetal*, and *metalloid* mean.

Why It's Important

The periodic table is an organized list of the elements that compose all living and nonliving things known to exist in the universe.

Review Vocabulary

chemical property: any characteristic of a substance that indicates whether it can undergo a certain chemical change

New Vocabulary

- periodic table
- group
- electron dot diagram
- period

Organizing the Elements

On a clear evening, you can see one of the various phases of the Moon. Each month, the Moon seems to grow larger, then smaller, in a repeating pattern. This type of change is periodic. *Periodic* means "repeated in a pattern." The days of the week are periodic because they repeat themselves every seven days. The calendar is a periodic table of days and months.

In the late 1800s, Dmitri Mendeleev, a Russian chemist, searched for a way to organize the elements. When he arranged all the elements known at that time in order of increasing atomic masses, he discovered a pattern. **Figure 8** shows Mendeleev's early periodic chart. Chemical properties found in lighter elements could be shown to repeat in heavier elements. Because the pattern repeated, it was considered to be periodic. Today, this arrangement is called the periodic table of elements. In the **periodic table**, the elements are arranged by increasing atomic number and by changes in physical and chemical properties.

Figure 8 Mendeleev discovered that the elements have a periodic pattern in their chemical properties.

Table 4 Mendeleev's Predictions

Predicted Properties of Ekasilicon (Es)	Actual Properties of Germanium (Ge)
Existence Predicted: 1871	Actual Discovery: 1886
Atomic mass = 72	Atomic mass = 72.61
High melting point	Melting point = 938°C
Density = 5.5 g/cm ³	Density = 5.323 g/cm ³
Dark gray metal	Gray metal
Density of EsO ₂ = 4.7 g/cm ³	Density of GeO ₂ = 4.23 g/cm ³

Mendeleev's Predictions Mendeleev had to leave blank spaces in his periodic table to keep the elements properly lined up according to their chemical properties. He looked at the properties and atomic masses of the elements surrounding these blank spaces. From this information, he was able to predict the properties and the mass numbers of new elements that had not yet been discovered. **Table 4** shows Mendeleev's predicted properties for germanium, which he called ekasilicon. His predictions proved to be accurate. Scientists later discovered these missing elements and found that their properties were extremely close to what Mendeleev had predicted.

 **Reading Check** How did Mendeleev organize his periodic table?

Improving the Periodic Table Although Mendeleev's arrangement of elements was successful, it did need some changes. On Mendeleev's table, the atomic mass gradually increased from left to right. If you look at the modern periodic table, shown in **Table 5**, you will see several examples, such as cobalt and nickel, in which the mass decreases from left to right. You also might notice that the atomic number always increases from left to right. In 1913, the work of Henry G. J. Moseley, a young English scientist, led to the arrangement of elements based on their increasing atomic numbers instead of an arrangement based on atomic masses. This new arrangement seemed to correct the problems that had occurred in the old table. The current periodic table uses Moseley's arrangement of the elements.

 **Reading Check** How is the modern periodic table arranged?

Organizing a Personal Periodic Table

Procedure

1. Collect as many of the following items as you can find: feather, penny, container of water, pencil, dime, strand of hair, container of milk, container of orange juice, square of cotton cloth, nickel, crayon, quarter, container of soda, golf ball, sheet of paper, baseball, marble, leaf, paper clip.
2. Organize these items into several columns based on their similarities to create your own periodic table.

Analysis

1. Explain the system you used to group your items.
2. Were there any items on the list that did not fit into any of your columns?
3. Infer how your activity modeled Mendeleev's work in developing the periodic table of the elements.

2 Teach

Purpose Students classify objects that are very different. **L2**

 **Logical-Mathematical**

Materials a variety of objects that can be sorted into several categories

Teaching Strategy A wide variety of objects will force the students to work harder to find common traits.

Analysis

1. Answers will vary but possible groups include metal objects, coins, organic items, spheres, liquids, and writing implements.
2. Answers will vary.
3. Just as Mendeleev searched for similarities and repeating patterns among the elements, students searched for commonalities among the objects to place them in groups.

Assessment

Performance Provide students with an assortment of bolts, screws, and nails. Have them build another periodic table using these items. Use **Performance Assessment in the Science Classroom**, p. 121.

 **Reading Check**

Answer He arranged the elements by increasing atomic mass and aligned them in columns based on chemical and physical properties.

Answer by atomic number

Teacher FYI

Mendeleev's Predictions Mendeleev predicted several elements in addition to ekasilicon. These included successful predictions of ekaaluminum and ekaboron, which were

later found to be gallium and scandium, and unsuccessful predictions of ekaniobium and ekacesium, which do not exist. The prefix *eka* is Sanskrit for the numeral one.

Quick Demo

Singing the Elements

Materials compact disc, record, or tape of *An Evening Wasted with Tom Lehrer*, compact disc player, record player, or tape player

Estimated Time 10 minutes

Procedure Play the fourth song, *The Elements*. The song's lyrics, which are set to a Gilbert and Sullivan tune, contain the names of the chemical elements. Make a list of puns related to the names or symbols of the elements. Ask students to come up with the correct elements. Some examples include policeman, **copper**; smelliest element, **Pu**; foolish prisoner, **silicon**.

Teacher FYI

Nonmetallic The elements have an increasing nonmetallic characteristic as you read from left to right across the table. Along the stair-step line are metalloids, which have properties of both metals and nonmetals.

Activity

Atomic Mass Chart Have students list the elements in the first six periods that would be out of sequence if the chart were arranged by atomic mass. **Ar and K, Co and Ni, Te and I** **L2** **LS** **Logical-Mathematical**

Visual Learning

Periodic Table Which element has an average mass greater than 75 but less than 79? **selenium** Is it possible to have more than one element that could fit that restriction? **No; based on average masses, there are no missing atomic numbers from 33 to 34 to 35.**

Table 5 Periodic Table of the Elements

Columns of elements are called groups. Elements in the same group have similar chemical properties.

The first three symbols tell you the state of matter of the element at room temperature. The fourth symbol identifies elements that are not present in significant amounts on Earth. Useful amounts are made synthetically.

SECTION 3 The Periodic Table 591

IDENTIFYING

Misconceptions

A Disadvantage Mendeleev did not have the advantage of knowing atomic structure when he made his periodic chart. Electrons were not discovered until the late 1890s. His chart was based on mass and properties of the elements.

Use an Analogy

Orderly Classification Remind students that orderly classification allows them to enter a music store and quickly find a desired selection without examining every CD in the store. The periodic table gives chemists the same advantage when they are looking for elements with particular properties.

Fun Fact

Hydrogen, by its electron arrangement, is part of Group 1. However, because it has only one electron in an energy level that can hold two electrons, it has its own unique set of properties.

LAB DEMONSTRATION

Purpose to choose a criterion for arranging items

Materials 5 clear plastic cups, water, blue food coloring

Preparation Add an equal amount of water to each cup. Add 1 drop of food coloring to cup 1, 2 drops to cup 2, and so on. Make one

with $3\frac{1}{2}$ drops and put it aside.

Procedure Mix the order of the cups and display them. Have students place the cups in a sequence. Display the solution made with $3\frac{1}{2}$ drops of food coloring and ask them to place it in its proper location.

Expected Outcome The sequence may be

from diluted to concentrated or the opposite.

Assessment

How does this activity demonstrate the thinking Mendeleev used for his chart? He made a sequence of chemical elements based on their properties and could tell where new discoveries fit in. L2

Research Physicist The amount of energy an electron contains determines its behavior. Physicists can apply this knowledge to the fields of nuclear energy, electronics, optics, and communications.

Research Have students research who employs research physicists and what the future job outlook statistics are for this career.

Visual Learning

Figure 9 Point out to students that this diagram is not intended to represent relative sizes of the electrons, atom, or nucleus.

Reading Strategy

Think-Aloud Choose a challenging piece of text, such as Electron Dot Diagrams, and read it aloud while interjecting questions and strategies to aid comprehension. Show students how to use related figures to help with comprehension. Then have students find their own difficult passages and practice close reading with a partner.

Caption Answer

Figure 9 number of electrons in the outer energy level

Research Physicist The study of nuclear interactions is shared by chemists and physicists. Research physicists use their knowledge of the physical laws of nature to explain the behavior of the atom and its composition. Explain in your Science Journal why physicists would study the amount of energy that electrons contain.

Figure 9 Energy levels in atoms can be represented by a flight of stairs. Each stair step away from the nucleus represents an increase in the amount of energy within the electrons.

Explain what determines the chemical properties of an element.

The Atom and the Periodic Table

Objects often are sorted or classified according to the properties they have in common. This also is done in the periodic table. The vertical columns in the periodic table are called **groups**, or families, and are numbered 1 through 18. Elements in each group have similar properties. For example, in Group 11, copper, silver, and gold have similar properties. Each is a shiny metal and a good conductor of electricity and heat. What is responsible for the similar properties? To answer this question, look at the structure of the atom.

Electron Cloud Structure You have learned about the number and location of protons and neutrons in an atom. But where are the electrons located? How many are there? In a neutral atom, the number of electrons is equal to the number of protons. Therefore, a carbon atom, with an atomic number of 6, has six protons and six electrons. These electrons are located in the electron cloud surrounding the nucleus.

Scientists have found that electrons within the electron cloud have different amounts of energy. Scientists model the energy differences of the electrons by placing the electrons in energy levels, as in **Figure 9**. Energy levels nearer the nucleus have lower energy than those levels that are farther away. Electrons fill these energy levels from the inner levels (closer to the nucleus) to the outer levels (farther from the nucleus).

Elements that are in the same group have the same number of electrons in their outer energy levels. It is the number of electrons in the outer energy level that determines the chemical properties of an element. It is important to understand the link between the location on the periodic table, chemical properties, and the structure of the atom.

Differentiated Instruction

Challenge Each energy level contains sublevels, which in turn contain atomic orbitals. Have students find out more about the distribution of electrons in sublevels and atomic orbitals. Have students make a chart showing the information found about sublevels. The first energy level has only one sublevel, while the second level has two sublevels, and the third has three. The first sublevel in any level contains one *s* orbital,

which can contain up to two electrons. The second sublevel in any level contains three *p* orbitals. Each *p* orbital can contain up to two electrons, so this sublevel can contain a maximum of six electrons. The third sublevel contains five *d* orbitals, each of which can contain up to two electrons, so this sublevel can contain up to ten electrons. The fourth sublevel contains seven *f* orbitals, each of which can contain up to two electrons, so this sublevel can contain up to fourteen electrons. **L3** **IS** Linguistic **P**

Energy Levels Energy levels are named using the numbers one to seven. The maximum number of electrons that can be contained in each of the first four levels is shown in **Figure 9**. For example, energy level one can contain a maximum of two electrons. Energy level two can contain a maximum of eight electrons. Notice that energy levels three and four contain several electrons. A complete and stable outer energy level will contain eight electrons. In elements in periods three and higher, additional electrons can be added to inner energy levels, although the outer energy level contains only eight electrons.

Rows on the Table Remember that an atomic number found on the periodic table is equal to the number of electrons in an atom. Look at **Figure 10**. The first row has hydrogen with one electron and helium with two electrons both in energy level one. Because energy level one is the outermost level containing an electron, hydrogen has one outer electron. Helium has two outer electrons. Recall from **Figure 9** that energy level one can hold only two electrons. Therefore, helium has a full or complete outer energy level.

The second row begins with lithium, which has three electrons, two in energy level one and one in energy level two. Lithium has one outer electron. Lithium is followed by beryllium, with two outer electrons, boron with three, and so on until you reach neon, with eight outer electrons. Again, looking at **Figure 9**, energy level two can hold only eight electrons. Therefore, neon has a complete outer energy level. Do you notice how the row in the periodic table ends when an outer energy level is filled? In the third row of elements, the electrons begin filling energy level three. The row ends with argon, which has a full outer energy level of eight electrons.

Reading Check How many electrons are needed to fill the outer energy level of sulfur?

Hydrogen 1 H	
Lithium 3 Li	Beryllium 4 Be
Sodium 11 Na	Magnesium 12 Mg

					Helium 2 He
Boron 5 B	Carbon 6 C	Nitrogen 7 N	Oxygen 8 O	Fluorine 9 F	Neon 10 Ne
Aluminum 13 Al	Silicon 14 Si	Phosphorus 15 P	Sulfur 16 S	Chlorine 17 Cl	Argon 18 Ar

Scienceonline
Topic: Atomic Energy Level Structure
Visit fl.gpscience.com for Web links to information about the structure of atomic energy levels.
Activity Draw a diagram that details how the energy levels are structured.

Figure 10 One proton and one electron are added to each element as you go across a period in the periodic table.
Explain what the elements in the last column share in relation to their outer energy levels.

Fun Fact

The maximum number of electrons in a level is $2n^2$, where n is the level number. For example, when $n = 3$ there can be a maximum of $2(3^2) = 18$ electrons.

Discussion

Row Questions In which row do you find the metalloid germanium? **fourth row** Which row contains the fewest elements? **first row** Which row probably contains the largest atoms on the periodic table? **seventh row** **L2**

Visual-Spatial

IDENTIFYING
Misconceptions
Lanthanides and Actinides Students may be confused by the depiction of the last two rows of the periodic table below the rest of the table. These two rows, called the lanthanides and actinides, respectively, are shown below to allow the table to be displayed in a manner that is easy to read.

Caption Answer

Figure 10 Each element in the last column has a full outer-energy level.

Reading Check

Answer two additional electrons

Curriculum Connection

Music In music, the syllables *do, re, mi, fa, sol, la, ti, do* give the pitches of the diatonic scale. Have students find out how this scale is similar to the periodic table. The scale *do, re, mi, fa, sol, la, ti, do* can be related to Li, Be, B, C, N, O, F, and Na in the periodic table. Na repeats the properties of Li just as the second *do* is one octave higher than the first *do*. **L2** **Auditory-Musical**

Differentiated Instruction

Learning Disabled Obtain samples of several elements, such as tin, copper, sulfur, silver, and aluminum. Have students examine and record the characteristics of each element. They should look for such properties as color, hardness, texture, and brittleness. They can play a game in which one student lists the characteristics and another identifies the element. **L1**

Activity

Energy Levels With a periodic table prominently displayed, or while students look at the one in the text, select various elements by name and atomic number. Have students determine the correct number of outer level electrons and write the dot diagram on the board. Do not use the elements from Groups 3–12 for this activity. These groups, called the transition elements, have their new electrons added to a lower energy level. [L2]

 **Visual-Spatial**

Use an Analogy

Wearing a Hat Remind students that when atoms gain or lose electrons, they become charged, negatively if they gain electrons and positively if they lose electrons, but the atoms retain their identity because the number of protons in the nucleus remains the same. This is analogous to the way a person can wear a hat and easily take it off without losing his or her identity. [L2]

Fun Fact

The elements in Group 18, known as the noble gases, had no recognized compounds until 1962 when xenon and fluorine were combined. Since then, other noble gas compounds have been formed. As recently as 2000, argon was found to combine. These are rare cases. In nature, noble gases are found uncombined.

Reading Check

Answer All members of a group have the same number of electrons in their outer energy level.

Caption Answer

Figure 11 determines the chemical properties of an element

Figure 11 The elements in Group 1 have one electron in their outer energy level. This electron dot diagram represents that one electron.

Explain why the outer electrons of an element are important.

H•

Li•

Na•

K•

Rb•

Cs•

Fr•

Figure 12 Electron dot diagrams show the electrons in an element's outer energy level.

The electron dot diagram for Group 17 consists of three sets of paired dots and one single dot.

Sodium combines with chlorine to give each element a complete outer energy level in the resulting compound.

Neon, a member of Group 18, has a full outer energy level. Neon has eight electrons in its outer energy level, making it unreactive.

Electron Dot Diagrams Did you notice that hydrogen, lithium, and sodium each have one electron in their outer energy levels? Elements that are in the same group have the same number of electrons in their outer energy levels. These outer electrons are so important in determining the chemical properties of an element that a special way to represent them has been developed. American chemist G. N. Lewis created this method while teaching a college chemistry class. An **electron dot diagram** uses the symbol of the element and dots to represent the electrons in the outer energy level. **Figure 11** shows the electron dot diagram for Group 1 elements. The electron configuration of an atom determines how that atom reacts with other atoms. Electron dot diagrams also are used to show how the electrons in the outer energy levels are bonded when elements combine to form compounds.

Same Group, Similar Properties The elements in Group 17, the halogens, have electron dot diagrams similar to chlorine, shown in **Figure 12**. All halogens have seven electrons in their outer energy levels. Because all of the members of a group on the periodic table have the same number of electrons in their outer energy levels, group members will undergo chemical reactions in similar ways.

A common property of the halogens is the ability to form compounds readily with elements in Group 1. Group 1 elements each have only one electron in their outer energy levels. **Figure 12** shows an example of a compound formed by one such reaction. The Group 1 element, sodium, reacts easily with the Group 17 element, chlorine. The result is the compound sodium chloride, or NaCl, ordinary table salt.

Not all elements will combine readily with other elements. The elements in Group 18 have complete outer energy levels. This special configuration makes Group 18 elements relatively unreactive. You will learn more about why and how bonds form between elements in later chapters.

Reading Check

Why do elements in a group undergo similar chemical reactions?

Active Reading

Jigsaw In this collaborative learning technique, individuals become experts on a portion of a text and share their expertise with a small group, called their home group. Everyone shares responsibility for learning the assigned reading. Assign each person in each home group an expert number. Have students gather into the expert groups that correspond to the numbers

they were assigned. Have them read, discuss, and master chapter concepts and determine how best to teach them to their home groups. Have students return to their home groups and share the content they learned in their expert groups. Have students use this strategy to help them learn about the characteristics of elements and how they are grouped on the periodic table. [L2]

Regions on the Periodic Table

The periodic table has several regions with specific names. The horizontal rows of elements on the periodic table are called **periods**. The elements increase by one proton and one electron as you go from left to right in a period.

All of the elements in the blue squares in **Figure 13** are metals. Iron, zinc, and copper are examples of metals. Most metals exist as solids at room temperature. They are shiny, can be drawn into wires, can be pounded into sheets, and are good conductors of heat and electricity.

Those elements on the right side of the periodic table, in yellow, are classified as nonmetals. Oxygen, bromine, and carbon are examples of nonmetals. Most nonmetals are gases, are brittle, and are poor conductors of heat and electricity at room temperature. The elements in green are metalloids or semimetals. They have some properties of both metals and nonmetals. Boron and silicon are examples of metalloids.

Reading Check What are the properties of the elements located on the left side of the periodic table?

A Growing Family Scientists around the world are continuing their research into the synthesis of elements. In 1994, scientists at the Heavy-Ion Research Laboratory in Darmstadt, Germany, discovered element 111. As of 1998, only one isotope of element 111 had been found. This isotope had a life span of 0.002 s. In 1996, element 112 was discovered at the same laboratory. As of 1998, only one isotope of element 112 had been found. The life span of this isotope was 0.00048 s. Both of these elements are produced in the laboratory by joining smaller atoms into a single atom. The search for elements with higher atomic numbers continues. Scientists think they have synthesized elements 114 and 116. However, the discovery of these elements has not yet been confirmed.

Figure 13 Metalloids are located along the green stair-step line. Metals are located to the left of the metalloids. Nonmetals are located to the right of the metalloids.

ScienceOnline

Topic: New Elements
Visit fl.gpescience.com for Web links to information about newly synthesized elements.

Activity Write an article explaining how several new elements were synthesized and who synthesized them.

Reading Check

Answer The elements on the left side of the table are metals, which are solids at room temperature, shiny, and good conductors of heat and electricity. Hydrogen is an exception to these properties.

Virtual Labs

Periodic Table How is the structure of an atom related to its position on the periodic table?

Inquiry Lab

Purpose to explore compounds that may form between elements
Possible Materials index cards or paper and markers
Estimated Time one class session
Teaching Strategies

- Students make cards with electron dot diagrams for elements in Groups 1–2 and 13–17.
- Students will need more than one card for some elements.
- Students can predict compounds that will form between the elements using electron dot diagrams.
- Have students make a list of the compounds that may form.

For additional inquiry activities, see *Science Inquiry Labs*.

Post Reading

Science Journal Have students work in pairs as they review the history of the periodic table. In their own words, have them respond to this prompt: What characteristics of the elements led to the periodic table being named *periodic*? Have students discuss their responses with different partner.

Science Journal

New Elements Have students research and identify the newest synthesized element. Have them write in their Science Journals the element's name, atomic number, isotope, half-life, and where the element was discovered. **L2** **LS** **Linguistic**

Content Background

A star in Earth's galaxy explodes as a supernova about once a century. The most famous supernova of this galaxy occurred in 1084. The explosion was so powerful that it could be seen during the day and its brightness lasted for weeks.

Figure 14 Scientists think that some elements are found in nature only within stars.

Elements in the Universe

Using the technology that is available today, scientists are finding the same elements throughout the universe. They have been able to study only a small portion of the universe because it is so vast. Many scientists believe that hydrogen and helium are the building blocks of other elements. Atoms join together within stars to produce elements with atomic numbers greater than 1 or 2, the atomic numbers of hydrogen and helium. Exploding stars, or supernovas, shown in **Figure 14**, give scientists evidence to support this theory. When stars reach the supernova stage, which is characterized by a massive explosion, a mixture of elements, including the heavy elements such as iron, are flung into the galaxy. Many scientists believe that supernovas have spread the elements that are found throughout the universe. Some of these elements are found only in trace amounts in Earth's crust as a result of uranium decay. Others have been found only in stars.

3 Assess

DAILY INTERVENTION

Check for Understanding

Visual-Spatial Have students draw a generic dot diagram for elements in Groups 1, 2, and 13-18. [L2]

Reteach

Classifying Elements Using a poster-sized periodic table, point to various elements and ask students to identify the group number and period number of each element and classify it as a metal, nonmetal, or metalloid.

[L2] **Visual-Spatial**

Assessment

Performance Gather pens and pencils from the class and have students suggest ways to group them that place similar ones together. Then have students arrange the pens and pencils by approximate mass in a pencil-periodic table. Give students a new pen or pencil and ask them to decide where to place it in the table. How is this similar to Mendeleev's activities? He arranged chemical elements by mass and by properties and could predict and classify new elements. Use PASC, p. 121. [L2]

section 3 review

Summary

Organizing the Elements

- Mendeleev organized the elements using increasing atomic mass and chemical and physical properties.
- Mendeleev left blank spaces in his table to allow for elements that were yet undiscovered.
- Moseley corrected the problems in the periodic table by arranging the elements in order of increasing atomic number.

The Atom and the Periodic Table

- The vertical columns in the periodic table are known as groups or families. Elements in a group have similar properties.
- Electrons within the electron cloud have different amounts of energy.

Regions of the Periodic Table

- The periodic table is divided into these regions: periods, metals, nonmetals, and metalloids.
- Scientists around the world continue to try to synthesize new elements.

Self Check

1. **Identify** Use the periodic table to find the name, atomic number, and average atomic mass of the following elements: N, Ca, Kr, and W.
2. **List** the period and group in which each of these elements is found: nitrogen, sodium, iodine, and mercury.
3. **Classify** each of these elements as a metal, a nonmetal, or a metalloid and give the full name of each: K, Si, Ba, and S.
4. **Think Critically** The Mendeleev and Mosely periodic tables have gaps for the as-yet-undiscovered elements. Why do you think the table used by Mosely was more accurate at predicting where new elements would be placed?

Applying Math

5. **Make a Graph** Construct a circle graph showing the percentage of elements classified as metals, metalloids, and nonmetals. Use markers or colored pencils to distinguish clearly between each section on the graph. Record your calculations in your Science Journal.

section 3 review

1. N, nitrogen, 7, 14.007; Ca, calcium; 20, 40.078; Kr, krypton, 36, 83.798; W, tungsten, 74, 183.84
2. nitrogen, period 2, Group 15; sodium, period 3, Group 1; iodine, period 5, Group 17; mercury, period 6, Group 12
3. K, potassium, metal; Si, silicon, metalloid; Ba, barium, metal; S, sulfur, nonmetal
4. One could not be certain that the gaps in Mendeleev's table would be filled by only one element. However, Moseley's table was arranged by number of protons.

Therefore, if the gap were between two elements differing by two protons, only one element could fit.

5. The graph should indicate that about 79% of the elements are metals; about 7% are metalloids, and about 14% are nonmetals.

A Periodic Table of Foods

Real-World Problem

Mendeleev's task of organizing a collection of loosely related items probably seemed daunting at first. How will using your favorite foods to create your own periodic table be similar to the task that Mendeleev had?

Goals

- **Organize** 20 of your favorite foods into a periodic table of foods.
- **Analyze** and **evaluate** your periodic table for similar characteristics among groups or family members on your table.
- **Infer** where new foods added to your table would be placed.

Materials

11 × 17-in paper
12- or 18-in ruler
colored pencils or markers

Procedure

1. **List** 20 of your favorite foods and drinks.
2. **Describe** basic characteristics of each of your food and drink items. For example, you might describe the primary ingredient, nutritional value, taste, and color of each item. You also could identify the food group of each item such as fruits/vegetables, grains, dairy products, meat, and sweets.
3. **Create** a data table to organize the information that you collect.
4. Using your data table, construct a periodic table of foods on your sheet of paper. Determine which characteristics you will use to group your items. Create families (columns) of food and drink items that share similar characteristics on your table.

For example, potato chips, pretzels, and cheese-flavored crackers could be combined into a family of salty tasting foods. Create as many groups as you need. You do not need to have the same number of items in every family.

Conclude and Apply

1. **Evaluate** the characteristics you used to make the groups on your periodic table. Do the characteristics of each group adequately describe all the family members? Do the characteristics of each group distinguish its family members from the family members of the other groups?
2. **Analyze** the reasons why some items did not fit easily into a group.
3. **Infer** why chemists have not created a periodic table of compounds.

Communicating Your Data

Construct a bulletin board of the periodic tables of foods created by the class. Compare and contrast the tables.

LAB 597

Real-World Problem

Purpose Students create a periodic table to organize foods. [L2]

Logical-Mathematical

Process Skills classify, compare and contrast, sequence, make and use tables

Procedure

Time Required 30 minutes

Teaching Strategies Have references available from which students can find the nutritional content of foods, such as fruits, that have no labels.

Conclude and Apply

1. Answers will vary, but food items containing several major ingredients such as pizza or ice cream cones often present classification problems.
2. Individual foods such as mangos or tuna are easily grouped into the major food groups, but when food ingredients are combined into items such as cakes or soups, classification becomes difficult.
3. There are about 114 elements, many with common characteristics. There are millions of compounds, which makes a table of compounds impractical to construct and apply.

Assessment

Process Have students repeat the activity using only unprocessed foods. Does this make it easier or more difficult to divide foods into families? Use **Performance Assessment in the Science Classroom**, p. 121.

Communicating Your Data

Students may want to use a spreadsheet program to determine the layout of the class periodic table of foods for the bulletin board.

Real-World Problem

Internet Students use Internet sites that can be accessed at fl.gpscience.com. Students can post their findings on the site and get information from other schools around the country.

Non-Internet Sources In its entry for an element, an encyclopedia often will give the history of the discovery and naming of that element. Find books about the history of science, including biographies of famous scientists and descriptions of important discoveries and inventions.

Time Required about two days

Make a Plan

Preparation

Internet To run through the steps that the students will follow, visit fl.gpscience.com.

Non-Internet Sources Bring to class books on the history of chemistry and the history of science that describe how elements were discovered and named.

Goals

- **Research** the names and symbols of various elements.
- **Study** the methods that are used to name elements and how they have changed through time.
- **Organize** your data by making your own periodic table.
- **Study** the history of certain elements and their discoveries.
- **Create** a table of your findings and communicate them to other students.

Data Source

Internet Lab

Visit fl.gpscience.com for more information about naming elements, elements' symbols, and the discovery of new elements, and for data collected by other students.

What's in a name?

Real-World Problem

The symbols used for different elements sometimes are easy to figure out. After all, it makes sense for the symbol for carbon to be C and the symbol for nitrogen to be N. However, some symbols aren't as easy to figure out. For example, the element silver has the symbol Ag. This symbol comes from the Latin word for *silver*, *argentum*. How are symbols and names chosen for elements?

Make a Plan

1. Make a list of particular elements you wish to study.
2. **Identify** the symbols for these elements.
3. **Research** the discovery of these elements. Do their names match their symbols? Were they named after a property of the element, a person, their place of discovery, or a system of nomenclature? What was that system?

Alternative Inquiry Lab

Real-World Connection To make this Lab an Inquiry Lab, give the students more personal investment into the problem by connecting it to the real world. Tell the students that they must devise a system for naming new elements that are discovered. Have them devise a naming system that can

be used by scientists world wide. After students have devised their system, have them compare and contrast their system to the system devised by the International Union of Pure and Applied Chemistry. [L2]

Using Scientific Methods

Follow Your Plan

1. Make sure your teacher approves your plan before you start.
2. Visit the Web site provided for links to different sites about elements, their history, and how they were named.
3. **Research** these elements.
4. Carefully record your data in your Science Journal.

Analyze Your Data

1. **Record** in your Science Journal how the symbols for your elements were chosen. What were your elements named after?
2. **Construct** an element key that includes the research information that you found for your elements.
3. Make a chart of your class's findings. Sort the chart by year of discovery for each element.
4. How are the names and symbols for newly discovered elements chosen? Make a chart that shows how the newly discovered elements will be named.

Conclude and Apply

1. **Compare** your findings to those of your classmates. Did anyone's data differ for the same element? Were all the elements in the periodic table covered?
2. **Explain** the system that is used to name the newly discovered elements today.
3. **Explain** Some elements were assigned symbols based on their name in another language. Do these examples occur for elements discovered today or long ago?

Communicating Your Data

Find this lab using the link below. Post your data in the table provided. **Compare** your data to those of other students.

Internet Lab
fl.gpscience.com

LAB 599

Communicating Your Data

Students can build an interactive periodic table of the elements. Have them use the computer and a Web page development program to display the periodic table. Suggest they design the table so that when an element is clicked, the computer will display information about the origin of the name and symbol for that element.

Assessment

Portfolio Ask students to prepare written reports of their findings about the way elements were named hundreds of years ago and the way they are named today. Have them include in their reports their original hypotheses and discussions of how the information they found proved or disproved their hypotheses. Use **Performance Assessment in the Science Classroom**, p. 157.

Follow Your Plan

Teaching Strategies

- Suggest that students include in their lists of elements to study some elements discovered long ago and some elements discovered more recently.
- Suggest that each student study at least ten elements.
- Have books on Greek and Roman mythology available so students can learn more about the characters from these myths for whom some of the elements are named.

Analyze Your Data

1. Students should report how the names and symbols of the elements were determined.
2. The student's element key should resemble the element key on the periodic table.
3. Answers will vary.
4. Different scientific organizations have created naming recommendations for newly discovered elements.

Conclude and Apply

1. Student data for the same element should not differ. Have students write their names next to the elements they researched to see if all the elements were investigated.
2. The International Union of Pure and Applied Chemistry has specific recommendations for giving names and symbols to newly-discovered elements.
3. elements discovered long ago

Content Background

Air trapped in ice cores contains traces of whatever the lower atmosphere contained at the time the ice formed. Large increases in the concentration of sulfates indicate volcanic activity. Changes in types of pollen provide clues to general trends in temperature.

Discussion

Finding Clues Why do we know more about what caused the Greenland colony to vanish today than the people who discovered the colonists missing? **Possible answer:** The scientific knowledge and technology to extract and analyze ice cores did not exist until recently. [L2]

Historical Significance

Climate change is not a relic of the past, but a continuing cyclical process. Obtain for the class a cross sectional slab of tree trunk or a large photo of one. The tree should be approximately three feet in diameter. Make sure you know where the tree grew and when. Have students determine how long the tree lived by counting the rings and then determine where and when it lived. With this knowledge, students can research local temperatures over the lifespan of the tree and plot them using small flags on pins placed at the appropriate rings. Discuss with students the relation between ring size and temperature. Discuss any anomalous variations in ring size and other possible environmental conditions that may have been responsible for them.

A scientist inspects an ice core sample from the Greenland Ice Sheet. The samples are stored in a freezer at -36°C .

Picture this: It's 1361. A ship from Norway arrives at a Norwegian settlement in Greenland. The ship's crew members hope to trade its cargo with the people living there. The crew members get off the ship. They look around. The settlement is deserted. More than 1,000 people had vanished!

New evidence has shed some light on the mysterious disappearance of the Norse settlers. The evidence came from a place on the Greenland Ice Sheet over 600 km away from the settlement. This part of Greenland is so cold that snow never melts. As new snow falls, the existing snow is buried and

turns to ice. By drilling deep into this ice, scientists can

Air bubbles and dirt trapped in ice provide clues to Earth's past climate.

recover an ice core. The core is made up of ice formed from snowfalls way, way back in time.

By measuring the ratio of oxygen isotopes in the ice core, scientists can estimate Greenland's past air temperatures. The cores provide a detailed climate history going back over 80,000 years. Individual ice layers can be dated much like tree rings to determine their ages. The air bubbles trapped within each layer are used to learn about climate variations. Dust and pollen trapped in the ice also yield clues to ancient climates.

A Little Ice Age

Based on their analysis, scientists think the Norse settlers moved to Greenland during an unusually warm period. Then, in the 1300s, the climate started to cool and a period known as the Little Ice Age began. The ways the Norse people hunted and farmed were inadequate for survival in this long chill. Because they couldn't adapt to their colder surroundings, the settlers died out.

Research Report Evidence seems to show that Earth is warming. Rising temperatures could affect our lives. Research global warming to find out how Earth may change. Share your report with the class.

Research Report Research periods of glaciation over the history of Earth and discuss the cycles in light of present climate conditions. You might want to construct a timeline for students showing Earth's average temperatures at different points in time and the percentage of Earth's surface covered with ice at those times. [L2]

Resources for Teachers and Students

"Core Values. (Samplings)." *Natural History*, March, 2003

Reviewing Main Ideas

Section 1 Structure of the Atom

1. A chemical symbol is a shorthand way of writing the name of an element.
2. An atom consists of a nucleus made up of protons and neutrons surrounded by an electron cloud, as shown in the figure to the right.
3. Quarks are particles of matter that make up protons and neutrons.
4. The model of the atom changes over time. As new information is discovered, scientists incorporate it into the model.

Section 2 Masses of Atoms

1. The number of neutrons in an atom can be computed by subtracting the atomic number from the mass number.
2. The isotopes of an element are atoms of the same element that have different numbers of neutrons. The figure below shows the isotopes of hydrogen.

3. The average atomic mass of an element is the weighted-average mass of the mixture of its isotopes. Isotopes are named by using the element name, followed by a dash, and its mass number.

Section 3 The Periodic Table

1. In the periodic table, the elements are arranged by increasing atomic number, resulting in periodic changes in properties. Knowing that the number of protons, electrons, and atomic number are equal gives you a partial composition of an atom.
2. In the periodic table, the elements are arranged in 18 vertical columns, or groups, and seven horizontal rows, or periods.
3. Metals are found at the left of the periodic table, nonmetals at the right, and metalloids along the line that separates the metals from the nonmetals, as shown below.

4. Elements are placed on the periodic table in order of increasing atomic number. A new row on the periodic table begins when the outer energy level of an element is filled.

FOLDABLES Use the Foldable that you made at the beginning of the chapter to help you review properties of atoms and the periodic table.

Reviewing Main Ideas

Summary statements can be used by students to review the major concepts of the chapter.

Assessment

Assessment Transparency Properties of Atoms and the Periodic Table Chapter 19				
Directions: Carefully review the table and answer the following questions.				
Characteristics of Some Alkaline Earth Metals				
Element	Atomic number	Mass number	Melting point (°C)	Boiling point (°C)
Magnesium	12	24	651	1105
Calcium	20	40	842	1494
Strontium	38	88	769	1384
Barium	56	137	725	1640

1. According to the table, which alkaline Earth metal has a mass number greater than 100?
 A. Magnesium C. Strontium
 B. Calcium D. Barium
2. According to the table, which element has the LOWEST atomic number?
 F. Magnesium H. Strontium
 G. Calcium J. Barium
3. According to the table, which element has the HIGHEST melting point?
 A. Magnesium C. Strontium
 B. Calcium D. Barium
4. The number of neutrons in the nucleus of an atom is equal to the mass number minus the atomic number. According to this definition and the table, how many neutrons are in the nucleus of a strontium atom?
 L2 20 38 50 81

FOLDABLES

Have students use their Foldables to review the content of the chapter. On the back of the paper, have students write a paragraph about how the atomic model looks today.

Using Vocabulary

1. periodic table
2. isotopes
3. Average atomic mass
4. nucleus
5. quarks
6. period
7. mass number
8. electron cloud

Checking Concepts

 group p. 592 quark p. 579
 * **isotope** p. 586

* FCAT Vocabulary

Complete the statement with the correct vocabulary word or phrase.

1. Mendeleev created an organized table of elements called the _____.
2. Two elements with the same number of protons but a different number of neutrons are called _____.
3. _____ is the weighted-average mass of all the known isotopes for an element.
4. The positively charged center of an atom is called the _____.
5. The particles that make up protons and neutrons are called _____.
6. A(n) _____ is a horizontal row in the periodic table.
7. The _____ is the sum of the number of protons and neutrons in an atom.
8. In the current model of the atom, the electrons are located in the _____.

Checking Concepts

Choose the word or phrase that best answers the question.

9. In which state of matter are most of the elements to the left of the stair-step line in the periodic table?
 A) gas C) plasma
 B) liquid D) solid

10. Which term describes a pattern that repeats?
 A) isotopic C) periodic
 B) metallic D) transition

11. Which element has similar properties to those of neon?
 A) aluminum C) arsenic
 B) argon D) silver

12. Which term describes boron?
 A) metal C) noble gas
 B) metalloid D) nonmetal

13. How many outer-level electrons do lithium and potassium have?
 A) one C) three
 B) two D) four

14. Which is NOT found in the nucleus of an atom?
 A) electron C) proton
 B) neutron D) quark

15. The atomic number of rhenium is 75. The atomic mass of one of its isotopes is 186. How many neutrons are in an atom of this isotope?
 A) 75 C) 186
 B) 111 D) 261

Use the photo below to answer question 16.

16. Which scientist developed this atomic model?
 A) Bohr C) Rutherford
 B) Dalton D) Thomson

Interpreting Graphics

- 17. Construct** As a star dies, it becomes more dense. Its temperature rises to a point at which He nuclei are combined with other nuclei. When this happens, the atomic numbers of the other nuclei are increased by 2 because each gains the two protons contained in the He nucleus. For example, Cr fuses with He to become Fe. Copy and complete the concept map showing the first four steps in He fusion.

- 18.** Copy and complete the concept map below.

Thinking Critically

- 19. Infer** Lead and mercury are two pollutants in the environment. From information about them in the periodic table, determine why they are called heavy metals.

- 20. Explain** why it is necessary to change models as new information becomes available.
- 21. Infer** Why did scientists choose carbon as a base for the atomic mass unit? Which isotope of carbon did they use?
- 22. Infer** Ge and Si are used in making semiconductors. Are these two elements in the same group or the same period?
- 23. Explain** Using the periodic table, predict how many outer level electrons will be in elements 114, 116, and 118. Explain your answer.
- 24. Infer** Ca is used by the body to make bones and teeth. Sr-90 is radioactive. Ca is safe for people, and Sr-90 is hazardous. Why is Sr-90 hazardous to people?

Applying Math

- 25. Solve One-Step Equations** The atomic number of yttrium is 39. The atomic mass of one of its isotopes is 89. How many neutrons are in an atom of this isotope?

Use the table below to answer question 26.

Electrons per Energy Level

Energy Level	Maximum Number of Electrons
1	2
2	8
3	8
4	0

- 26. Use Tables** Use the information in Figure 9 to determine how many electrons should be in the second, third, and fourth energy levels for argon, atomic number 18. Copy and complete the table above with the number of electrons for each energy level.

Interpreting Graphics

- 17.** See student page.
18. See student page.

Thinking Critically

- 19.** Compared to many metals, both lead and mercury have large average atomic masses.
- 20.** Models must be updated to reflect the new information that is found. If the models are not updated, they are obsolete when the new information is found. The model would be useless.
- 21.** Student answers may vary. It is possible that carbon was chosen because living organisms contain a significant amount of carbon. carbon-12
- 22.** same group
- 23.** 114-4; 116-6; 118-8; because these elements are in groups 14, 16, and 18 respectively
- 24.** The radioactive nature of Sr can damage human cells.

Multiple Choice

1. D 4. C
2. D 5. C
3. C 6. D

Gridded Response

7. 125
8. 35.5 amu

Record your answers on the answer sheet provided by your teacher or on a sheet of paper. The assessed Florida Benchmark appears above the question.

Multiple Choice

1. Which group of elements on the periodic table do not combine readily with other elements?
- A. Group 1
B. Group 2
C. Group 17
D. Group 18

Use the illustration below to answer question 2.

Multiple Choice

2. Which of the regions shown on the periodic table contains mostly elements that are gases at room temperature?
- A. region 1
B. region 2
C. region 3
D. region 4

Test-Taking Tip

Have Breakfast The morning of the test, eat a healthy breakfast with a balanced amount of protein and carbohydrates.

3. Which scientist proposed the idea that atoms make up all substances?
- A. Aristotle
B. Dalton
C. Democritus
D. Galileo

Use the table below to answer question 4.

Element	Electrons in a Neutral Atom	Electrons in Outer Energy Level
Carbon	6	4
Oxygen	8	6
Neon	10	8
Sodium	11	1
Chlorine	17	7

Multiple Choice

4. Which element would you expect to be located in Group 1 of the periodic table?
- A. oxygen
B. neon
C. sodium
D. chlorine
5. The element nickel has five naturally occurring isotopes. Which of the following describes the relationship of these isotopes?
- A. same mass, same atomic number
B. same mass, different atomic number
C. different mass, same atomic number
D. different mass, different atomic number

6. Atoms of different elements are different because they have different numbers of what type of particle?

A. electrons
B. photons
C. protons
D. neutrons

Gridded Response

SCA.2.4.5

7. According to the periodic table, an atom of lead has an atomic number of 82. How many neutrons does lead-207 have?
8. About three out of four chlorine atoms are chlorine-35, and about one out of four is chlorine-37. What is the average atomic mass of chlorine?

Short Response

SCA.1.4.1

Use the illustration below to answer question 9.

SCA.1.4.5

9. The electron dot diagram above shows how a sodium atom, Na, combines with a chlorine atom, Cl, to form sodium chloride. What do the + and the - symbols indicate in the diagram?

SCA.1.4.5

10. Why isn't the mass of the electron included in the mass of an atom on the periodic table?

READ
INQUIRE
EXPLAIN

Extended Response

Use the illustration below to answer questions 11 and 12.

11. The illustration above shows the currently accepted model of atomic structure. Describe this model.
12. Compare and contrast the model shown above with Bohr's model of an atom.

SCA.1.4.1

13. How can you use the periodic table to determine the average number of neutrons an element has, even though the number of neutrons is not listed?
14. Describe how Dalton's modernization of the ancient Greeks' ideas of elements, atoms, and compounds provided a basis for understanding chemical reactions. Give an example.

Rubrics

For more help evaluating Short- and Extended-Response questions, see the rubrics on p. 9T.

Short Response

9. The + indicates that the sodium atom loses an electron, and the - indicates the chlorine atom gains an electron when the ionic bond forms.
10. You can determine the average number of neutrons by subtracting the atomic number from the average atomic mass.

Extended Response

11. A cloud of negatively-charged electrons moves in an area around the nucleus of the atom.
12. Bohr hypothesized that electrons travel in fixed orbits around the atom's nucleus. In the electron cloud model of an atom, the electrons do not follow fixed orbits.

Both models agree that the nucleus contains positively-charged protons and neutrons with no charge.

13. You can determine the average number of neutrons by subtracting the atomic number from the average atomic mass.

Section Focus

Section Focus Transparency **A Sea of Diamonds** **Chapter 20**

Over the past 100 million years, up to 100 million diamonds have been formed in the Earth's mantle. These diamonds are not the same as the diamonds you find in jewelry. They are much smaller, and they are much harder. They are also much more abundant than the diamonds you find in jewelry. They are found in a variety of places, including in the Earth's mantle, in the Earth's crust, and in the Earth's atmosphere.

L2

Section Focus Transparency **Earth Power!** **Chapter 20**

Earth's power is a result of the Earth's internal heat. This heat is generated by the Earth's core, which is made of molten iron and nickel. The heat is transferred to the Earth's mantle, which is made of solid rock. The mantle is divided into the upper mantle and the lower mantle. The upper mantle is the part of the mantle that is closest to the Earth's surface. The lower mantle is the part of the mantle that is furthest from the Earth's surface.

L2

Section Focus Transparency **Fossil Fascination** **Chapter 20**

Fossils are the remains of ancient life. They can be found in a variety of places, including in the Earth's crust, in the Earth's atmosphere, and in the Earth's oceans. Fossils can be used to learn about the Earth's history and the evolution of life. They can also be used to learn about the Earth's climate and the environment.

L2

Section Focus Transparency **Marvelous Marble** **Chapter 20**

Marble is a type of metamorphic rock. It is formed from limestone or dolomite. The process of forming marble involves heat and pressure. The heat causes the minerals in the rock to recrystallize, and the pressure causes the rock to become more compact. The result is a rock that is harder and more resistant to weathering than the original rock.

L2

This is a representation of key blackline masters available in the Teacher Classroom Resources. See Resource Manager boxes within the chapter for additional information.

Key to Teaching Strategies

The following designations will help you decide which activities are appropriate for your students.

- L1** Level 1 activities should be appropriate for students with learning difficulties.
- L2** Level 2 activities should be within the ability range of all students.
- L3** Level 3 activities are designed for above-average students.
- ELL** ELL activities should be within the ability range of English Language Learners.

COOP LEARN Cooperative Learning activities are designed for small group work.

LS Multiple Learning Styles logos, as described on page 12T, are used throughout to indicate strategies that address different learning styles.

P These strategies represent student products that can be placed into a best-work portfolio.

PBL Problem-Based Learning activities apply real-world situations to learning.

Assessment

Assessment Transparency **Earth Materials** **Chapter 20**

Directions:

1. Identify the type of rock or mineral shown in each picture.
 - ☐ Igneous
 - ☐ Sedimentary
 - ☐ Metamorphic
2. Write the name of the rock or mineral in the space provided.
 - ☐ Granite
 - ☐ Limestone
 - ☐ Quartzite
3. A mineral is a naturally occurring solid substance with a definite chemical composition.
 - ☐ True
 - ☐ False

L2

Teaching

Teaching Transparency **Using the Mohs Scale** **Chapter 20**

Directions:

Mohs Scale	Hardness	Hardness of Common Objects
1	(softest)	fingernail (2.5)
2.5 to 3.0		piece of copper (2.5 to 3.0)
4.5		iron nail (4.5)
5.5		glass (5.5)
6.5		steel file (6.5)
7.0		streak plate (7.0)
		hardest

SECTION • Minerals

Section 10
Unit 10
Lesson 10

Earth Materials

What You'll Learn

- describe minerals and their uses
- identify minerals by physical properties
- understand the rock cycle

• Before You Read

Think about the foods you eat. You would use *flavor* to describe the difference between two of your favorite foods. Look at the words in the box and answer the questions.

Authentic Questions Ask your class to discuss the questions.

• Read to Learn

Common Elements

What is included in Earth's crust?

Read the text and answer the questions.

• What You'll Learn

What is included in Earth's crust?

Science Content Background

section**Minerals**

1

Common Elements

An important idea is that all matter, not just minerals, is made up of very few of the known elements. Most minerals are composed of only eight elements; expand the list of elements to 15 and you'll cover Earth's atmosphere, oceans, and living things. These 15 elements are common, simple, and have an atomic mass of less than 30.

Most rock forming minerals are more complex variations of a simple form. For example, the many types of silicates are composed of the simple silicon-oxygen tetrahedron. The addition of small amounts of an impurity changes these structures and creates a new set of physical properties.

section**Igneous Rocks**

2

Crystalization Temperature

Magma can be thought of as a solution controlled by temperature. At a given temperature a mineral might exist as a solid or liquid. Magmas can be thought of as an element or an ionic soup. As the soup

cools, ions will slow down and begin to form mineral crystals. Bowen's Reaction Series explains which minerals form first. The soup now has chunks of minerals. These chunks have a melting temperature that is higher than the temperature of the magma and will not melt as the magma continues to cool. Should temperatures rise, the minerals will melt in the reverse order from which they crystallized.

Magma rich in low-mass elements will produce minerals such as quartz or potassium feldspar, and will be low in density. Such low-density magmas produce continental crustal rocks such as granite. This density difference accounts for Earth's less-dense crust and denser mantle. The mantle is composed of minerals with higher densities such as olivine and pyroxene.

If magma cools rapidly, elements have less time to form large crystals. Crystal size, or texture, provides information on the rate of formation. The first rocks to be formed from a magma can be determined by their composition. These two factors—texture and composition—are key to classifying and interpreting igneous rocks.

Section 3 Sedimentary Rocks **Texture and Composition Clues**

The classification of sedimentary rock is based mainly on texture, followed by composition. Textural factors in detrital sedimentary rocks are particle size, shape, and sorting (range of size variation). These factors provide clues to the energy level and possible changes of the transporting medium.

Generally, large-sized clasts equate to high energy—mountain streams or beaches with heavy surf. Smaller sizes equate to low energy—swamps, lake bottoms, or deltas.

Shape factors give clues to the distance of transport. Angular clasts indicate near source locations. Well-rounded clasts indicate long distances of transport or longer periods of residence in an abrasive environment.

Size variation or sorting indicates variability of energy. Well-sorted clasts, all roughly the same size, indicate a consistent energy level. Beach sand tends to be well-sorted because wave action winnows away fine clasts and abrades and reduces larger clasts.

Composition depends on the nature of the parent rock. Rocks from the eastern United States yield a light-colored, quartz-rich sand like that of the Florida beaches. The basalt of Hawaii produces black sand. Poor sorting usually indicates a constant supply of new clasts or an extreme variability in energy levels. Chemical and organic sedimentary rocks tend to be composed of one mineral.

Section 4 Metamorphic Rocks and the Rock Cycle **Degree of Metamorphism**

Texture and composition are used equally when classifying metamorphic rock. Metamorphic rocks are first sorted by degree of foliation. Generally, as the degree of metamorphism increases, the rock will display a more-pronounced foliation pattern and will contain more mica minerals. Non-foliated metamorphic rocks tend to exhibit increased growth in grain size. The grains are often similar in size and composition. To avoid confusion in identifying igneous and metamorphic rocks, recall that igneous rocks have a broader range of grain sizes and mineral composition.

Teacher to Teacher

Nancy Bridge
Olympia High School
Orlando, Florida

For a hands-on experience with the rock cycle, I give each lab group four different colored crayons and a pencil sharpener. Students sharpen the crayons and collect the shavings on a piece of tag-board paper. This is the sediment step. Have students fold the tag board over, place it on the floor, and step on it. This is the sedimentary step. You still can see the individual colors and shapes but they cling together. Students bring the tag-board pockets to the teacher. The teacher places a warm iron (heat and pressure) on top of the tag-board pocket, which slightly melts the crayons together and makes a harder rock sample—the metamorphic step. We place a sample from the metamorphic step on a piece of foil, put it on a hot plate, and completely melt it. You no longer can distinguish any colors but it has changed into a new color—the igneous step.

Mountain of Oxygen

We often think of oxygen as being in the air we breathe, but we also walk on it everyday. By weight, almost half of Earth's crust is oxygen. Imagine half the weight of this mountain being made of oxygen!

Science Journal In your Science Journal, list ten of the most important materials you can think of and where you think they come from.

606

Theme Connection

Law of Conservation of Mass This law states that mass can be neither created nor destroyed during chemical changes. In the rock cycle, minerals are being transformed by physical and chemical processes into different rock types, without the loss of the starting mass.

About the Photo

Gem of the Rockies Glacier-studded mountains tower above Maligne Lake, in Jasper National Park, Canada. These mountains are made of sedimentary rocks and a metamorphic rock called quartzite. Common minerals include silica, feldspar, mica, and olivine. Glaciers scour valley floors and grind rocks into rock flour. In the lake, this suspended material distorts light into emeralds and blues.

Start-Up Activities

Earth Materials at Home and School

You come in contact with Earth materials every day. Many of the objects around you are Earth materials, or items processed using minerals or rocks as raw materials.

1. Obtain several items from your teacher.
2. Make a three-column table on a separate sheet of paper.
3. In the first column, list each item.
4. In the second column, decide whether each item listed is a natural Earth material or a product made from Earth materials.
5. In the third column, indicate whether the item is found at home, school, or both places.
6. **Think Critically** Select three of the items in your first column and imagine that they no longer exist. Explain how you could cope without these materials. What other materials could be used instead?

FOLDABLES™ Study Organizer

Textures Make the following Foldable to help you organize the types of textures in igneous, sedimentary, and metamorphic rocks.

- STEP 1** Fold a sheet of paper in half lengthwise. Make the back edge about 2 inches longer than the front edge.

- STEP 2** Turn the paper so the fold is on the bottom. Then fold it into thirds.

- STEP 3** Unfold and cut only the top layer along both folds to make three tabs.

- STEP 4** Label the Foldable as shown

Making a Concept Map As you read the chapter, write about and illustrate the texture types shown by each group of rocks represented in your concept map.

Purpose Use the Launch Lab to introduce students to the idea that most of the manufactured objects we use today require raw materials from Earth. **L2 Kinesthetic**

Preparation Prepare a collection of different objects to show the class or compile a list of common items for the class to consider.

Materials Suggested objects: paper clip, beverage can, plastic pen cap, piece of ceramic tile, piece of glass, cotton cloth, straw basket, leather item, wood item

Teaching Strategies

- Show the class an item and allow students to record their responses.
- Give students an object and have them explain their decisions to the class.

Think Critically

Possible answer: Students should speak of using alternative materials, such as using plastics instead of metals.

Assessment

Oral Have students formulate a list of Earth materials that we use today, but may run out of in the future. Have them include steps that could be taken to avoid this problem.

FOLDABLES™ Study Organizer

**Dinah Zike
Study Fold**

Student preparation materials for this Foldable are available in the Chapter **FAST FILE** Resources.

INTERACTIVE CHALKBOARD An editable Microsoft® PowerPoint® presentation is available on Interactive Chalkboard CD-ROM.

Bellringer

Section Focus Transparencies also are available on the Interactive Chalkboard CD-ROM.

L2 ELL

Section Focus Transparency **A Sea of Diamonds** **Chapter 20**

Over the past 100 million years, up to 1,400 meters have eroded from the land's surface, sending billions of carats of diamonds on a trip to the sea. An estimate of diamonds eroded from just one mine, South Africa's Kimberly mine—the "Big Hole," is 500,000 carats! Rivers carried most of the eroded diamonds to the Atlantic Ocean, although about ten percent were stored in the alluvial deposits of the drainage systems. Because powerful ocean waves break poorer quality diamonds, only the best percent of marine diamonds are of gem quality. That makes the Atlantic coast the focus of intense mining activity.

1. How are diamonds formed?
2. Why are diamonds so valuable?
3. How do diamonds fit the definition of a mineral?

L2

Reading Preview

Tie to Prior Knowledge

Compounds Have students recall that compounds are composed of two or more different elements. Minerals are compounds found naturally on Earth. L2

Vocabulary Chart Have students develop a chart containing the new vocabulary words. Most of the terms are properties of minerals. Have students fill out the chart as they read, explaining the characteristics represented by each term.

Reading Guide

What You'll Learn

- **Describe** characteristics of all minerals.
- **Identify** common minerals using physical properties.
- **Compare and contrast** some conditions of mineral formation.

Why It's Important

Minerals are a source of raw materials used to support civilization.

Review Vocabulary

ionic bond: attraction formed between oppositely charged ions in an ionic compound

New Vocabulary

- mineral
- cleavage
- fracture
- hardness
- streak
- magma

Common Elements

You're familiar with the periodic table of elements. Of the first 92 elements, 90 are found in Earth, and of these, only a small number combine to make up most of the common minerals in Earth's crust. **Table 1** lists these important elements. Most of the chemical formulas of common minerals contain some of these elements.

Composition of Earth's Crust The crust is the outermost layer of Earth. It includes all continental material and the material that forms the ocean bottom. The crust extends down tens of kilometers beneath the continents, but it is much thinner where it makes up the ocean bottom and material below, as shown in **Figure 1**.

Table 1 Major Elements in Earth's Crust

Element	Percent (by mass)	Element	Percent (by mass)
Oxygen	46.6%	Sodium	2.8%
Silicon	27.7%	Potassium	2.6%
Aluminum	8.1%	Magnesium	2.1%
Iron	5.0%	All others	1.5%
Calcium	3.6%

Chemical Element Building Blocks Imagine Earth's chemical parts being like a set of interlocking blocks. In the set you are given lots of common types of blocks from which you can make thousands of forms. But, you are given only a few of the special blocks. The bulk of the forms you build consist of the common blocks. Elements and minerals in Earth's crust are a lot like the block set. For example, most minerals of the crust, whether beneath the land surface or ocean water, contain abundant oxygen and silicon.

What's a mineral?

Remember that atoms of different elements can bond chemically to form compounds. A **mineral** is a naturally occurring element or compound that is inorganic, solid, and has a crystalline structure. In addition, minerals have predictable chemical compositions that are indicated as single elements or chemical formulas. For example, the native element gold is a mineral with chemical formula Au. Similarly, the compound fluorite is a mineral that contains Ca and F in a 1:2 ratio, resulting in chemical formula CaF_2 .

Physical Properties

A mineral has a characteristic set of physical properties, but some of these properties can differ from sample to sample. For example, some minerals come in several different colors. This color variation may be due to chemical impurities in the mineral. This is true for the gem varieties of the mineral corundum, Al_2O_3 . Ruby is red corundum, and sapphire is blue corundum. Ruby contains more of the element chromium, which substitutes for Al in the crystalline structure. You should take care when observing mineral properties, particularly when studying their colors.

Figure 1 The crust and a thin layer of the upper mantle make up the lithosphere, which means rock sphere. The lithosphere floats on a dense, plasticlike layer called the asthenosphere.

SECTION 1 Minerals 609

Teacher FYI

Gemstone Market Diamonds are often viewed as the king of gemstones. There is a diamond cartel, which means that a few producers in the world strictly control the price of diamonds. The mining, grading, cutting, and marketing of diamonds do not allow for price to reflect demand. Colored stones, such as emeralds, rubies and sapphires, are not subject to this control and therefore change in value according to the effects of supply and demand.

Differentiated Instruction

English-Language Learners Have students create a dual-language glossary for common rock and mineral names. Having hand specimens available to illustrate the glossary could be helpful. **L2**

Visual-Spatial

Curriculum Connection

Geography Have students prepare a world map showing the distribution of metal (iron, copper, aluminum, gold, silver) or valuable mineral (emerald, ruby, diamond) production. Discuss whether the countries where these are found are enjoying economic growth because of this.

Make A Model

Construct a model of the atomic arrangement of a common mineral, such as sodium chloride (NaCl) or calcium carbonate (CaCO_3). **L2** **ELL** **LS** **Visual-Spatial, Kinesthetic**

Activity

Special Properties of Minerals Discuss with students that some minerals have distinct properties that help in their identification. Provide small groups with samples of halite, calcite, magnetite, specular hematite, and sphalerite. In addition, provide them with dilute HCl, a small magnet and a streak plate. If possible, demonstrate the effect that fluorescent light has on calcite. Encourage students to discover the special properties that each of these minerals has. Halite tastes salty, calcite fizzes with HCl, magnetite is magnetic, specular hematite is silver but shows a reddish-brown streak, and sphalerite is brown but steaks pale yellow and the streak smells like sulphur. Calcite appears orange under fluorescent light.

✓ Reading Check

Answer Quartz fractures, but does not cleave.

IDENTIFYING

Misconceptions

Cleavage v. Crystals Students may confuse a crystal face for a cleavage plane. Explain, using a quartz crystal as a guide, that crystal faces are not cleavage features.

Figure 2 Because mica has one direction of cleavage, it can be separated in layers.

Atom Arrangement Some physical properties are controlled by the orderly arrangement of atoms in a mineral's structure. This orderly pattern is what makes a mineral crystalline. The arrangement of atoms and the bonds between them can reflect the way a mineral breaks, how hard it is, and what type of crystal shape it has.

How Minerals Break When minerals break along planes that cut across relatively weak chemical bonds, a smooth, flat surface is created. The ability of a mineral to do this is the physical property called **cleavage**. All parallel cleavage planes define a single direction of cleavage. The mica family of minerals exhibits only one direction of cleavage, as shown in **Figure 2**. Other minerals may show two or more different directions of cleavage, as in **Figure 3**. If this happens, those different planar directions have to meet each other at an angle.

Some minerals do not split along well-defined flat surfaces. In such cases, a mineral will break unevenly. This type of irregular break is called **fracture**. Quartz is an example of a common mineral that does not cleave, but exhibits fracture. This physical property is a key aspect in distinguishing quartz from other minerals.

✓ **Reading Check** What distinguishes quartz from other minerals?

610 CHAPTER 20 Earth Materials

Visual Learning

Figure 2 Observe the mica in the photo. What can you say about the chemical bonds that form this mineral? Because the mineral splits into sheets, you can say that the bonds are weak. **L2** **LS** **Visual-Spatial**

Teacher FYI

Cleavage Cleavage doesn't have to display entire planar surfaces. Imagine the corner of a box projecting above a surface. You can see three cleavage faces; top, end, and side. It is not necessary to see the opposite planar surface of these to infer their presence.

Hardness Bonds connecting atoms in materials often have different strengths. When you scratch a mineral with another material you will be breaking bonds and leaving a scratch. The physical property that measures resistance to scratching is called **hardness**. You can compare the hardness of different materials by applying scratch tests and using Mohs Scale, as shown in **Table 2**. When a hardness test is performed by rubbing two objects together, the softer of the two will wear away.

Today, you might be using a pencil that takes advantage of the softness of a mineral. The graphite in the core of some pencils has one plane of cleavage and very weak bonds. The weak bonds make the lead soft. As you write with the pencil, thin plates of graphite are left on your paper and the pencil becomes dull.

Luster and Streak The way a mineral reflects light is the physical property known as luster. Two main types of luster, metallic and nonmetallic, help subdivide minerals and often give a clue about their compositions. Just as you might guess, metallic luster minerals reflect light in a way that a metal surface might, such as the shiny chrome on a car or bicycle. Nonmetallic luster, shown in **Figure 4**, includes descriptions of all other types, such as those minerals that shine like glass or appear earthy or waxy.

The color of a mineral in powdered form is called **streak**. The streak of a mineral may be the same color as the mineral specimen, but when a mineral shows different colors or types of luster, the streak powder color generally stays the same, which helps identify the mineral. A streak test is performed by rubbing a mineral on a white porcelain tile.

Table 2 Mohs Scale of Hardness	
1. Talc	6. Feldspar
2. Gypsum (fingernail 2.2)	7. Quartz (streak plate 7.0)
3. Calcite (copper penny 3.2)	8. Topaz
4. Fluorite	9. Corundum
5. Apatite (glass plate 5.5)	10. Diamond

Figure 4 The mineral on the left produces a glassy luster; the mineral on the right produces a metallic luster.

Quick Demo Testing for Hardness

Materials penny, steel nail, wire nail, glass plate.

Estimated Time 20 minutes

Procedure Demonstrate the technique for determining hardness.

- The test is for resistance to scratching.
- The pressure used is similar to that for writing.
- Show testing in several directions on the same surface of the specimen. Often, specimens contain more than one mineral. Be sure to test different surfaces of the same mineral.
- Caution students to always hold either the sample or the testing materials on the table. They should always place the glass plate on the table, never in their hands. **L2** **ELL** **Visual-Spatial**

Discussion

What makes diamonds, sapphires, and rubies so valuable? There are two possible answers. **Rarity** for those minerals that have extreme value; supply and demand for all the others. Quartz sand has little value because it is so abundant; extremely pure quartz, which is rare, has a higher value because of its use in making computer chips.

Activity

Before having a formal lab experience with minerals, have students sort the minerals they will use in the lab into groups of their choice. Have them explain their sorting criteria. **Students will most likely use color.** Use several colors of quartz as an example to explain the problem of using color alone. **L2**

ELL **Visual-Spatial**

Visual Learning

Figure 4 What color streak would the two minerals shown here produce? Streak testing is generally useful only for metallic minerals. Can you explain why this is so? **The streak produced by non-metallic minerals is usually white, while metallic minerals produce streaks that range from black to grey to even reddish-brown.** A colored streak provides more information about a particular mineral than a white streak does.

Mini LAB

Purpose Students will learn and identify the shape of salt (NaCl) crystals. **L2** **ELL** **Visual-Spatial**

Materials table salt, magnifying glass

Analysis

1. sketches of cubes
2. Cubes may stick together to form rectangles.
3. cubic; The length of all of the sides of the smallest particle are equal.

Assessment

Content Have students imagine the placement of the sodium and chlorine atoms to form a cube and to form a repeated structure of cubes.

Mini LAB

Identifying Salt's Crystal System

Procedure

1. Sprinkle a small quantity of salt onto a dark surface.
2. Using a magnifying lens, observe the individual grains of salt.

Analysis

1. Make a sketch showing the shapes of several salt grains.
2. Why are some of the grains more elongated than others?
3. To which crystal system does salt belong? Support your answer with details from the text.

Figure 5 Minerals can be classified using six basic crystal forms.

Crystal Shape The orderly internal arrangement of atoms in a mineral often is indicated by its external crystal shape. In fact, some minerals take on a geometric shape that is a larger version of their internal atomic arrangement. Even though many unique shapes are exhibited by mineral crystals in nature, each can be sorted into one of the six crystal systems, as shown in **Figure 5**. The types of symmetry shown by the crystal are key elements in determining the crystal system to which a mineral belongs.

Mineral Formation

A mineral crystal grows as atoms are added to its surfaces, edges, or corners. The types of atoms that are added depend on what atoms are available in the growing crystal's surroundings. Growth also is controlled by how fast atoms can migrate to the crystal and by the temperature and pressure conditions of the surroundings. Some ways that minerals form include precipitation from hot, water-rich fluids, solidification from molten rock material, and evaporation of water rich in dissolved salts at low temperatures near Earth's surface.

Minerals from Hot Water Some minerals are produced from hot-water solutions rich in dissolved mineral matter. You know that sugar dissolves fastest in hot water. As hot water cools, its atoms slow down and atoms of dissolved material are able to form chemical bonds. Minerals often form around the edges of hot springs, as shown in **Figure 6**. When hot water passes through cracks in cooler rock, minerals may form within the cracks. The cracks become lined and filled with mineral matter. Sometimes, veins or halos of concentrated minerals like gold, silver, or copper are produced in fractures.

Figure 6 Hydrothermal minerals form on the rims of hot springs.

Reading Strategy

Summarize Have students compose a summary paragraph in which they describe how scientists identify minerals by their properties. Remind students to explain each mineral property by using the mineral charts they created earlier.

Teacher FYI

Common Minerals and Crystal Systems The six crystal systems can be difficult to visualize. Sometimes the crystal takes the form of the system. For example, halite and calcite belong to the cubic and triclinic systems, respectively. A well-formed quartz crystal has six sides and belongs to the hexagonal system. Biotite, which occurs in sheets, belongs to the monoclinic system. Remember that identification of minerals seldom is based on identifying its crystal system.

Differentiated Instruction

Learning Disabled Some students may have a difficult time envisioning dissolved minerals in solution. Demonstrate the concept of evaporation and precipitation with a simple activity using salt and warm water. Have students dissolve 2–3 teaspoons of salt in 200 mL of warm water and stir until dissolved. Explain that the

mineral halite (salt) is now in solution. Pour the water into a shallow Petri dish and allow it to evaporate overnight. Explain that the water evaporated into the air (became water vapor) and the substance that remains on the dish is halite. It precipitated from the solution as the water evaporated.

Minerals from Magma Molten rock material found inside Earth is called **magma**. As magma cools, atoms slow down and begin to arrange into an orderly structure. When the temperature of magma drops well below the solidification temperature of a mineral, crystals of that particular mineral may form and grow.

Reading Check *How do minerals form in magma?*

Minerals from Evaporation Minerals also form from water at Earth’s surface. When water slowly evaporates, concentrated dissolved mineral material may be left behind to form crystals. You might have seen films of material left behind in a pan that once was filled with water. Crusty material is left on the surface of the pan after the water evaporates.

Mineral Groups

About 3,800 minerals have been identified in nature. Some minerals are so common that they are called rock-forming minerals. Recall that few elements are needed to make up almost the entire crust of Earth. Similarly, a few important mineral groups make up most of Earth’s crust.

Silicates The atomic arrangement and composition of minerals allow them to be sorted into groups. Among these, the most important by volume of Earth’s crust are the silicate groups.

Most minerals contain silica. Silica is a common term for a compound that contains silicon plus oxygen or silicon dioxide (SiO₂). The mineral quartz is pure silica that has crystallized. In silicate minerals, the elements silicon and oxygen bond together to form a geometric structure called a tetrahedron, as shown in **Table 3**. Other metal atoms can attach to the oxygen atoms. Most silicate minerals contain silicon, oxygen, and one or more other elements.

Si-O Bond The silicon-oxygen tetrahedron is the base unit for the silicates in the nonliving world. Carbon chains are fundamental units for living things. Research carbon chains and compare and contrast them with the Si-O tetrahedrons.

Reading Check

Answer When magma is cooled well below the solidification temperature of the minerals, atoms arrange themselves into orderly groups and solids form.

Si-O Bond Compare and contrast carbon chains with Si-O tetrahedrons. Both carbon and silicon are in Group 14 of the periodic table. Both elements form chains. However, carbon forms covalent bonds with many elements and often produces flexible molecular structures. In the Si-O tetrahedron, the bond between silicon and oxygen is an ionic bond, which often produces a rigid structure.

Table 3 Silicate Minerals		
Mineral	Photos	Silicate Structure
Olivine		 Single tetrahedron
Pyroxene group (Augite)		 Single chains
Amphibole group (Hornblende)		 Double chains
Micas		 Sheets
Feldspars		 Three-dimensional networks
Quartz		

Misconceptions

Mineral Precipitation Students may think that mineral matter gets sprayed or spread on the surface as hot water sprays or flows from a spring. The process is more complex. Minerals such as calcium and bicarbonate are dissolved in the hot water. Below the surface, the water is under pressure, which keeps the minerals in solution. At the surface, pressure is less. Carbon dioxide, which under pressure is dissolved in the water, escapes as a gas. This leaves the carbonate to combine with calcium, forming calcium carbonate as a precipitate. The chemical equation is as follows:

$$\text{Ca}^{2+} + 2\text{HCO}_3^- \rightarrow \text{CO}_2 \text{ (gas)} + \text{CaCO}_3 + \text{H}_2\text{O}$$

Fun Fact

Silica, which is pure quartz, has a wide variety of uses. It is used to make glass, added to tires to extend their life, added to highway asphalt to harden it, used in crystal as the time keeping element in watches, and is the foundation material in making computer chips.

Using Science Words

Word Meaning Introduce the word *phyllo* to the students. It means “leaf” in Greek. Phyllo dough is thin, sheet-like dough used to make a variety of pastries and foods. Challenge the students to determine which type of silicate the mineral mica is and explain why it is classified as such. **Mica is a phyllosilicate. These are made of sheets of silica tetrahedra that are weakly joined together. Mica occurs as sheets that are easily peeled apart. Thus, it is just like phyllo dough.**

Inquiry Lab

Mineral Search

Question How many things in your home are made from important silicate and non-silicate minerals?

Possible Materials items found at home, textbook

Estimated Time 30 minutes

Teaching Strategies

- Have students use their textbook and other sources to research and prepare a list of silicate minerals and non-silicate minerals that are commonly used for household items.
- Explain that quartz, a silicate, is used in glass, watches, clocks, computers, televisions, and electronic games. Talc, a silicate, is used in talcum powder, paint, ceramics, paper, and rubber.
- Important non-silicates include fluorite (toothpaste), calcite (cement and antacids), graphite (pencil lead), gypsum (drywall), and halite (table salt). Other non-silicates include some gemstones and metals such as iron (used in steel), copper, zinc, aluminum, tin, gold, and silver.

For additional inquiry activities, see *Science Inquiry Lab Manual*.

Science *inquiry*

Topic: Economic Minerals

Visit fl.gpescience.com for Web links to information about uses for minerals.

Activity Make a table for at least ten minerals. Your table headings should include *Common Minerals*, *Occurrences*, and *Uses or Products*.

Silicate Structures You probably have watched buildings go up in your neighborhood. All the buildings are put together using similar construction materials. What really makes them different is how these materials are put together. Silicate mineral groups are similar. Silicates all contain silicon-oxygen tetrahedrons that are linked together in different ways.

The simplest silicate structures have silicon-oxygen tetrahedrons that are not linked together. By joining silicon-oxygen tetrahedrons together, chains, sheets, and three-dimensional framework structures can form, as shown in **Table 3**. Keep in mind that each group of silicates has a different structure, but most contain the silicon-oxygen tetrahedron as a basic structural unit.

Minerals of the Crust Several important silicate groups form most of Earth's crust. Quartz and some feldspar group minerals, shown in **Table 3**, are relatively low in density and form at relatively low temperatures compared to other silicate minerals. Together, quartz and feldspar group silicates make up most of Earth's continental crust.

In contrast, Earth's oceanic crust is denser and contains a larger percentage of silicates whose tetrahedrons are not linked together as much. For example, chain silicates such as the pyroxene group, and single tetrahedron silicates of the olivine group, along with plagioclase feldspars, make up the majority of crust beneath the oceans.

Important Non-silicates Many important mineral groups are not silicates. These include the carbonates, oxides, halides, sulfides, sulfates, and native metals. The non-silicate groups are a source of many valuable ore minerals and building materials. To be an ore, a mineral must occur in large enough quantities to be economically recoverable. One example of an important ore of iron is the mineral hematite, an iron oxide. Aluminum comes in part from bauxite, a mixture of aluminum oxides. People eat salt processed from the halide mineral halite, and use calcite (a carbonate) to make cement. Common non-silicate minerals are shown in **Figure 7**.

✓ **Reading Check** To which mineral group does hematite belong?

Figure 7 Calcite, shown above, is a common mineral found in limestone. Hematite, below, is an ore used to produce iron and steel.

614 CHAPTER 20 Earth Materials

Fun Fact

Fun Fact Enrique Camarena Salazar was an American drug enforcement agent who was murdered and found buried on a ranch in Mexico. Forensic evidence and careful examination of the dirt found on his body determined that he had been killed somewhere else and had been moved to the ranch later.

Post Reading

Extended Research Have students research a mineral using library resources. Ask them to develop a report in which they discuss mineral extraction, uses, and properties. For example, a student may choose to study quartz, which is used in glass manufacturing and as a part of computers.

Mineral Uses

For centuries, humans have relied on minerals for their everyday needs, for example, humans have always needed salt. Civilizations have advanced themselves through the use of their mineral wealth. Think of the exploration and conflicts that took place over gold. Europeans spent vast sums of money and risked many lives to search for gold.

People use minerals either directly as objects of wealth, or as raw materials to make things. Those regions fortunate enough to have large quantities of hematite, iron ore, advanced rapidly. Think of all of the things made from iron and steel. Without iron there would be no machinery as we know it today for manufacturing goods.

Not all minerals need to provide metals to be valuable. Non-metallic minerals are valuable as well. For example, quartz is used to make glass and glass fibers. Glass fiber is used to make fiber optical cables. Most sands and gravels are largely quartz. When mixed with cement (calcite), quartz is used to make concrete. Think of all the things that are made of concrete.

INTEGRATE Language Arts

Salt Mining Because of its use as a preservative for food in ancient times, salt was a valuable resource. Salt has been collected by evaporating seawater and by mining deposits from below Earth's surface. Research the word *salary* in terms of its connection with salt.

INTEGRATE Language Arts

Salt Mining Because of its use as a food preservative, in ancient times salt was more valuable than gold. Through the ages salt has been collected by evaporating seawater or briny river water or through mining.

Research Have students research the origin of the word *salary*. *Salary* comes from Latin *salarium*, meaning "pension of salt," which comes from *sal* which means "salt." **ELL**

3 Assess

Section 1 Review

Summary

Common Elements

- Few elements form the bulk of materials in Earth's crust.

Mineral Properties

- A mineral is an inorganic solid with a predictable chemical composition.
- All minerals occur in nature and have orderly internal atomic arrangements.
- Physical properties of minerals may reflect their chemical composition and orderly atomic arrangement.

Mineral Formation and Mineral Groups

- Minerals crystallize mainly from fluids and molten rock material, as atoms come together to form crystalline structures.
- Minerals can be sorted into two broad categories: silicates and non-silicates.

Mineral Uses

- Civilization depends on minerals for a wide range of uses, from direct wealth to making products.

Self Check

- Determine** whether diamonds produced in laboratories are considered to be minerals.
- Describe** two ways that minerals form.
- Compare and contrast** mineral cleavage and mineral fracture.
- Explain** why it is useful to test more than one physical property when attempting to identify a mineral.
- Think Critically** What does the fact that mower blades become dull tell you about the hardness of the blades?

Applying Math

- Calculate Area** Imagine you have a halite cube that measures 3 cm on each edge. What is the total surface area of the cube?
- Calculate Area** Imagine cleaving the halite cube in question 6 exactly in half, perpendicular to one of its faces. What is the total surface area now?
- Analyzing Variables** What is the relationship between particle size and surface area for a given volume of material?

SECTION 1 Minerals 615

 Video Lab available for this lab.

 Real-World Problem

Purpose Students will gain experience in observation, classification, and use of a classification key. **L2**

Process Skills observe, evaluate, interpret data, record, collect data

Time Required Two 40-minute sessions

Safety Precautions

Pennies and steel nails are sufficient to establish hardness; glass plates can be omitted.

Place glass plates flat on surface and hold mineral sample in your hand.

Dispose of broken glass plates in proper containers.

 Procedure

Teaching Strategies Remind students to be open-minded in observations.

Troubleshooting If specimens are in short supply, give each group only two specimens at a time and rotate the specimens from group to group.

 Conclude and Apply

1. Some minerals have no outstanding properties.
2. Some minerals have outstanding and unique properties, such as mica with one plane of cleavage, galena with a high specific gravity, or halite with cubic cleavage.
3. Answers will vary. Students may list hardness, cleavage, fracture, and luster.
4. Answers will vary but may include color and luster.

LAB

Be a Mineral Detective

Detectives must gather facts and physical evidence to deduce the events that took place during a crime. Much like detectives, geologists gather physical evidence to better understand Earth processes. First, minerals are identified, and then their histories sometimes can be interpreted.

 Real-World Problem

How is it possible to distinguish similar-looking materials from each other?

Goals

- **Observe and record** physical properties of minerals.
- **Determine** mineral names using your observations and identification keys.

Materials

mineral samples	penny
unglazed porcelain tile	nail
Mohs hardness scale	glass plate
Reference Handbook, "Minerals"	

 Procedure

1. Set up a data table on your paper. Label the columns using, at least: *Mineral Number*, *Color*, *Hardness*, *Streak*, *Cleavage*, *Fracture*, *Other Observations* (like smell, feel, or heft), and *Mineral Name*.
2. Obtain numbered mineral specimens from your teacher. Observe each mineral and accurately record the data based on your tests for physical properties. Be descriptive and broad in your observations.

Hints: When determining hardness, test several different spots on the sample. Remember the hardness of your fingernail is a little more than 2; penny, a bit more than 3; steel nail, 5–6; glass, about 5–5.5. Minerals can have both cleavage and fracture at the same time. Cleavage is expressed as how many unique planar directions are present, and the angles formed when more than one direction occurs.

3. Using the Reference Handbook, "Minerals" at the back of your book, attempt to identify each unknown mineral. Your teacher may tell you when you are incorrect and allow you try again.

 Conclude and Apply

1. **Explain** why certain minerals seemed to be difficult to identify.
2. **Explain** why certain minerals seemed to be easy to identify.
3. **Determine** which physical properties were most reliable for identification overall.
4. **Determine** which physical properties seemed to be least reliable.

**Communicating
Your Data**

Compare your results with your classmates. Discuss what kind of mineral evidence a detective might obtain from a crime scene and how it might be used.

**Communicating
Your Data**

Detectives may compare mineral or soil particles found on the clothing, shoes, or other objects belonging to the accused with corresponding particles from the crime scene.

 Assessment

Oral Ask students to select a single identifying characteristic for each mineral they worked with. This will not be possible for some minerals. Reinforce the idea that identification relies on a set of characteristics. **L2**

Igneous Rocks

Reading Guide

What You'll Learn

- **Describe** the types of materials present in most rocks.
- **Explain** how and where igneous rocks form.
- **Classify** igneous rocks.

Why It's Important

Igneous rocks make up the majority of Earth's crust and mantle and contain clues about processes that form them.

Review Vocabulary

mixture: combination of two or more substances that can be physically separated

New Vocabulary

- rock
- texture
- intrusive igneous rock
- extrusive igneous rock

What's a rock?

A **rock** is a naturally formed consolidated mixture containing minerals, rock fragments, or volcanic glass. Most rocks contain crystals of minerals that may or may not be well-formed. Rocks are identified by their composition and texture. **Texture** is a description that includes the size and arrangement of the rock's components. The rock-making process is a continuous cycle. Part of this cycle involves rock formed from magma inside Earth.

Reading Check

What types of materials compose rocks?

Intrusive Igneous Rocks

Igneous rocks are those that form from molten rock material called magma. Geologists have termed igneous rocks from inside Earth **plutonic**, after Pluto, the Greek god of the underworld. Such rocks also are called **intrusive igneous rocks** because they form within, or push into, regions of Earth's crust, as shown in **Figure 8**.

Figure 8 These light-colored veins of intrusive igneous rock formed when molten rock material cut through surrounding rock layers.

Earth Power!

Chapter 20

Geothermal power plants are electricity-generating stations. They get their energy from hot water circulating deep underground in rocks heated by contact with magma. Geothermal plants are often located in geologically active locations, such as the Philippines and Indonesia. Geothermal power has great potential as an alternative source of energy to lessen the world's dependence on increasingly diminishing oil supplies.

1. How might a geothermal power plant gain access to the hot water underground?
2. How could magma heat water that comes in contact with it?

Do you think geothermal power could be the answer to the world's energy needs? Why or why not?

IDENTIFYING

Misconceptions

Magma A common misconception is that magma comes from the outer core. Some magma is formed in the asthenosphere. The asthenosphere is a semi-solid layer below the crust, within the upper part of the upper mantle. This magma is composed of the heavier, denser minerals such as olivine and pyroxene. Magma is also formed within the crust, particularly at convergent plate tectonic boundaries. This magma is less dense than that formed from the asthenosphere.

Use Science Words

Students often confuse the word freezing with being exclusive to the freezing of water at 0°C or 32° F. Ask what the freezing temperature of a magma is.

Stress that freezing is the action of going from a liquid to a solid; Hawaiian basalt flows freeze at temperatures in excess of 1,000° C. Also stress that freezing and melting temperatures are the same at a given pressure. **L1** **ELL**

L Linguistic

Caption Answer

Figure 9 Responses will vary, but mineral pairs should always be at approximately the same temperature level.

Figure 9 The Bowen's reaction series, shown below, illustrates the sequence in which minerals crystallize from magma at different temperatures.

Identify two pairs of minerals that are likely to be found in the same rock.

Nature of Magma As it passes through rock, magma might cause partial melting of the rock it intrudes. Geologists have learned that minerals melt at different temperatures, so some will melt when exposed to the thermal energy of the magma. This interaction between magma and surrounding rock can cause changes in the rock, contamination of the magma, or both.

You're familiar with the freezing of liquid water to form ice at 0°C on Earth's surface. Minerals freeze at very high temperatures, ranging from several hundred to more than 1,000°C. However, magmas generally must be cooled below the solidification temperature of a mineral in order for it to begin crystallizing.

Intrusive Igneous Rock Composition As crystals solidify in cooling magma, they use up certain atoms. High-temperature magmas tend to crystallize olivine and pyroxene group minerals and plagioclase feldspars first. These minerals are dense and tend to settle toward the bottom of the magma chamber. Late-forming, less dense minerals tend to solidify at lower temperatures and float to the top of the magma chamber. These relationships are shown in **Figure 9**.

618 CHAPTER 20 Earth Materials

Reading Strategy

Double-Entry Notes Have students divide a sheet of paper into two columns. In the left column, students will take notes from the text. The right column is reserved for reflections regarding the notes, such as connections to previous content, opinions, or questions.

Visual Learning

Figure 9 Observe that on the continuous series side of the diagram, the feldspar composition changes from sodium-rich at the low-temperature end to calcium-rich at the high-temperature end. Based on the minerals present at either end, what can you say about the color of sodium-rich and calcium-rich feldspar? **Sodium-rich feldspar is lighter in color than calcium-rich feldspar.** **L2** **Visual-Spatial**

Figure 10 Intrusive igneous rocks often can be distinguished from extrusive igneous rocks because of their large grain size.

The composition of intrusive igneous rocks gives you clues as to where in Earth they formed. Igneous rocks with abundant quartz generally are associated with continental crust, while those with little or no quartz generally are associated with deep locations in continental crust or with oceanic crust. The minerals found in the rock depend on what atoms were available in the magma. If a particular element is not present in the magma, then minerals requiring that element can't be formed.

✓ Reading Check Where might you find igneous rocks with little or no quartz?

Intrusive, Igneous Rock Texture Recall that texture describes the size and arrangement of rock components. In intrusive igneous rocks, grain size, which means the size of individual mineral crystals, gives you clues as to how fast magma cooled to form it. Magma that cools slowly, over many thousands or millions of years, allows atoms time to migrate about and form large crystals. Large grains are those big enough to see with the unaided eye. Such materials are termed coarse-grained, like the rock shown in **Figure 10**.

Classification of Intrusive Igneous Rocks It is worthwhile to consider a few igneous rock compositions that represent end-members of a large range in possible rock compositions. Rocks that are quartz-rich and contain potassium feldspar and plagioclase feldspar are called granite. Rocks with no quartz and abundant plagioclase feldspar and pyroxene are called gabbro. The low density of granite allows it to be a dominant rock in continental crust. Coarse-grained diorite is an igneous rock between granite and gabbro in composition. Peridotite is denser than gabbro, is composed mainly of olivine and pyroxene, and is thought to compose the bulk of Earth's uppermost mantle.

✓ Reading Check

Answer deep in continental crust or within oceanic crust

Use an Analogy

Crystals Forming in Magma At high temperatures, the ions in magma are far apart and movement from one area to another is easy. As magma cools, ions move closer to each other and eventually bond, forming crystals. These ions and crystals block the flow of any remaining ions. If a group of students represents ions, a single class in a gymnasium is free to move about. A student representing a silicon atom could easily migrate to find a student representing an oxygen atom. Imagine several classes in the gym with most of the students holding hands to represent chemical bonds in crystals. Any remaining silicon students will have difficulty migrating to find an oxygen ion student. **L2 ELL**

Quick Demo Igneous Characteristics

Materials large hand samples of common igneous rocks; granite, basalt, rhyolite, andesite, obsidian, and pumice

Estimated Time 20 minutes

Procedure Use the samples to reinforce the distinction between large and small crystal size, dark and light color, and vesicular and glassy textures. **L2 ELL**

LS Visual-Spatial

Differentiated Instruction

English-Language Learners Have the students describe what they see in the Quick Demo and/or Activity in their native language and immediately translate it to English.

Activity

Natural v. Synthetic Have students compare and contrast the crystallization of synthetic materials like metals and glass to the crystallization of igneous rocks. **Students should come to the conclusion that synthetic materials resemble natural glass and very fine-grained extrusive igneous rocks. This is due to the rapid cooling rates of the manufacturing processes.** [L2]

Discussion

Decorative Use of Granite Discuss with your students the common use of igneous rocks as countertops and flooring in homes and businesses. If possible, bring in samples of the types of rocks used. Ask students to explain why it is incorrect to call all of these samples granite. **Students should now know that there are many types of igneous rocks. Even though a rock is crystalline, it does not mean that it is granite. Dark-colored counters are actually forms of diorite or gabbro.**

Extrusive Igneous Rocks

When magma reaches Earth's surface, it is called lava. **Extrusive igneous rocks** are those that cool from lava that has erupted at Earth's surface, as shown in **Figure 11**. These rocks may have the same compositions as intrusive igneous rocks, but they always will have different textures. Rapid cooling causes small, microscopic grains to be present, or no grains at all. Volcanic glass represents an extreme in that it cools almost instantaneously, or is quenched, in air or water.

Magma often becomes contaminated with material that is melted from surrounding rocks as it passes through them on its way to Earth's surface. The greater the distance the magma travels, the more likely it will be contaminated. For example, magma traveling several kilometers to the surface is more likely to change in composition. Magma traveling a much shorter distance might remain unchanged. Another factor is the amount of time the magma was in contact with the surrounding rock material. If the magma is rapidly erupted at Earth's surface, it is less likely to have had enough time to melt the surrounding rock material. Composition of the surrounding rock material will also affect the extrusive magma. If the surrounding rock material is similar to the magma, contamination is less likely.

Figure 11 This type of lava, called pahoehoe, has a smooth, ropy surface.

Extrusive Igneous Rock Composition The compositions of extrusive igneous rocks is much like the compositions of their intrusive cousins. A magma rich in silica (SiO_2) forms granite if it cools slowly, and rhyolite if it cools rapidly. Similarly, gabbro's fine-grained volcanic counterpart is basalt, which is a common rock in Earth's oceanic crust. An extrusive rock intermediate in the amount of SiO_2 is andesite, the volcanic equivalent of intrusive diorite. Many intrusive igneous rock compositions have extrusive igneous rock equivalents.

Applying Math Use Percentages

EXTRUSIVE IGNEOUS ROCK CLASSIFICATION The amount of silica (SiO_2) in an extrusive rock formed when magma cools is used as a classification system. Basaltic rock contains 45 percent to 55 percent SiO_2 , andesitic rock contains 55 percent to 65 percent SiO_2 , and rhyolitic rock contains 65 percent to 75 percent SiO_2 . A 151-g rock is found to contain 89 g of SiO_2 . Based on the percentage of SiO_2 in this rock, how would you classify it?

IDENTIFY known values and the unknown value

Identify the known values:

$$151\text{-g rock} \xrightarrow{\text{means}} m_{\text{rock}} = 151 \text{ g}$$

$$89 \text{ g of } \text{SiO}_2 \xrightarrow{\text{means}} m_{\text{silica}} = 89 \text{ g}$$

Identify the unknown value:

$$\text{percentage of } \text{SiO}_2 \xrightarrow{\text{means}} \text{percent } \text{SiO}_2 = ? \%$$

SOLVE the problem

Divide the mass of SiO_2 by the total mass of the rock and multiply by 100%:

$$\text{percent } \text{SiO}_2 = \frac{m_{\text{silica}}}{m_{\text{rock}}} \times 100\% = \frac{89 \text{ g}}{151 \text{ g}} \times 100\% = 59\%$$

The rock should be classified as andesitic.

CHECK your answer

Does your answer seem reasonable? Check your answer by multiplying the percentage you calculated (expressed as a decimal) by the mass of the rock. The answer should be the mass of silica given in the problem.

Practice Problems

1. What is the greatest mass of SiO_2 that could be found in a 212-g rhyolitic rock?
2. A 120-kg basaltic boulder found in Hawaii contains 47 percent SiO_2 . How many kilograms of SiO_2 are in the boulder?

For more practice problems, go to page 879 and visit Math Practice at fl.gpscience.com.

Quick Demo

Identifying Igneous Rocks

Materials igneous rock samples, igneous rock identification chart showing both diagrammatic and percentage of mineral composition

Estimated Time 15 minutes

Procedure Beginning with granite, describe the overall color and texture of the sample and then show how it fits into the identification chart. **Granite is light in color and it has large crystals so it is positioned at the left end of the chart.** Work your way through rhyolite, andesite, diorite, gabbro, basalt, scoria, and obsidian, each time illustrating how the overall color, mineral composition, and grain size allow for its identification.

Applying Math

Math Standards

National: 1, 4, 9

Florida: MA.B.1.4.1

Teaching Strategy

Have students practice their estimating skills as a method of checking their answers. In the sample problem, 89 g of a 151-g rock is silica. $89 \text{ g}/151 \text{ g}$ is approximately $90 \text{ g}/150 \text{ g}$. $90/150 = 9/15 = 3/5 = 60\%$. Since 60% is very close to 59%, it appears that the problem was calculated properly.

Answers to Practice Problems

1. $75\% \times 212 \text{ g} = 159 \text{ g}$

2. $47\% \times 120 \text{ kg} = 56.4 \text{ kg}$

Fun Fact

Some names of rocks and minerals have something to do with how they look or how they formed. Obsidian refers to neither. Its name comes from the Latin word *obsidianus*, which is actually a misprint of the Latin word *obsidianus* (lapis). It literally means "stone of Obsius". Obsius, as described by Pliny, was a Roman man who allegedly found this rock in Ethiopia.

Science

Topic: Igneous Rock Textures

Visit fl.gpscience.com for Web links to information about igneous rock textures.

Activity Select gabbro and granite from plutonic microtextures. Make a detailed, colored sketch of each of the photomicrographs of these rocks. Label your drawings. Repeat the activity by selecting nepheline basalt and rhyolite from the volcanic microtextures file.

Reading Check

Answer Cooling starts off slowly, but finishes at a faster rate.

Caption Answer

Figure 12 Intrusive igneous rocks have larger crystals and, because individual mineral crystals can be seen, may exhibit a variety of colors. Extrusive igneous rocks have small crystals and are generally uniform in color.

Activity

Pumice Provide students with containers of a carbonated beverage and another solution that will not fizz. Have students pour each solution into a new container and observe. They should see gases released from the carbonated beverage and no gas release from the other solution. The frothy head is equivalent to pumice, while the liquid below it is a glass. They have the same composition but different textures.

Extrusive Igneous Rock Textures Rock has a limited ability to transfer thermal energy and so acts like an insulator, allowing magma to cool slowly. Should magma erupt into air or water, thermal energy loss is much faster. When magma nears the surface it meets up with much cooler surroundings. Depending on composition, magmas have temperatures ranging from about 650°C to 1,200°C. The surface of Earth might be 35°C on a hot day.

Recall that rapid cooling results in small crystals or no crystals at all and slow cooling results in large crystals, as shown in **Figure 12**. If cooling starts off slowly below the surface with large crystals, but then finishes at a faster rate to form small or no crystals, the extrusive rock is called a porphyry. If you observed a volcanic porphyry, you would see larger crystals embedded in a mass of small crystals or glass. The term *porphyritic* is used as an adjective to describe this texture. You might then have a porphyritic rhyolite or porphyritic basalt.

Reading Check What conditions cause a porphyritic texture to form?

Figure 12 Igneous rocks often are described as being basaltic or granitic. Basaltic rocks are dense and rich in magnesium and iron, but low in silica. Granitic rocks usually are less dense and are silica-rich, containing higher quantities of quartz.

Compare and contrast the textures and colors of extrusive igneous rocks and their intrusive counterparts.

	Granitic	Basaltic
Intrusive	 Granite	 Gabbro
Extrusive	 Rhyolite	 Basalt

Science Journal

Crystal Size and Igneous Intrusions A well-known igneous intrusion occurs in the Bighorn Mountains of Wyoming. It is called the Leopard Lode. It's central part consists of large, well-formed feldspar crystals that appear to be floating in a fine-grained, greenish-black background (ground-mass). The margins or sides of the intrusion consist of a fine-grained reddish/black

rock. Have students write a history of the Leopard Lode to explain the difference in grain sizes and why they occur where they do. **Accept all reasonable explanations.** The central portion is a porphyry—the groundmass is basalt. The sides are called a chill margin. As the intruding magma came in contact with the cold surrounding rock, it cooled quickly forming a fine-grained rock.

Volcanic eruptions can result in many different extrusive rock textures and forms as shown in **Figure 13**. Lava can be ejected into the air as large, streamlined blobs that solidify in flight called volcanic bombs, or smaller droplets known as lapilli. Solids of varying size from large blocks to ash can be expelled from a volcano.

Effect of Gases Should magma contain dissolved gases, the gases expand in response to decreasing pressure at the surface, escape, and break apart or disrupt the lava into ash flows. In addition, lava that flows across the surface also can have many tiny holes, somewhat like Swiss cheese. Such a texture is called vesicular, and it mainly forms near the top surface of a flow where gases escape. The extrusive rock pumice results when the holes are left behind. Some pumice has so many gas-bubble holes that its density is reduced and it can float in water.

Figure 13 Some volcanic bombs develop a streamlined shape when they are hurled rapidly through the air during a volcanic explosion.

Teacher FYI

Not all rocks that appear welded and vesicular are pumice. If they formed from ash and other ejected materials that became welded together, they are called tuff.

Post Reading

Chart Have students set up a chart with the headings *Intrusive Rocks* and *Extrusive Rocks*. In each column, students should list each rock type's characteristics and properties and include examples. For instance, granite is an intrusive rock and basalt is an extrusive rock.

3 Assess

section 2 review

Summary

What's a rock?

- Rocks are mixtures of a wide variety of natural materials.
- The composition and texture of a rock indicate how it formed.

Intrusive Igneous Rocks

- Intrusive igneous rocks form from magma below Earth's surface, cool slowly, and are coarse-grained.
- The composition of granite is similar to the composition of continental crust as a whole.

Extrusive Igneous Rocks

- Some extrusive igneous rocks form from lava at Earth's surface, cool rapidly, and are fine-grained or glassy.
- Other extrusive rocks are consolidated solid materials expelled from volcanoes.
- Oceanic crust is composed primarily of the extrusive igneous rock basalt.

Self Check

1. **List** the materials that can form a rock.
2. **Describe** how the texture of a porphyritic andesite indicates its cooling history.
3. **Discuss** what happens to the dissolved gases in magma as the magma ascends toward the surface of Earth.
4. **Explain** why you would not expect to observe an igneous rock with quartz and olivine in it.
5. **Think Critically** Lava flows that are relatively low in SiO_2 tend to have low viscosities, or flow easily. Name an igneous rock that you would expect to form from a low-viscosity lava flow. Explain your answer.

Applying Math

6. **Calculate Granite Volume** Granite occurs in very large masses called batholiths. The Sierra Nevada in California is a batholith made up of many separate intrusions. Suppose the mountain range averaged 8.33 km in thickness, extended 700 km north to south, and averaged 91.66 km wide. Approximately how many cubic kilometers of granite are in that mountain range?

DAILY INTERVENTION

Check for Understanding

Intrapersonal Display several igneous rocks. To confirm an understanding of igneous rock classification, have students state at least two criteria that they can use to correctly identify each sample. [L1]

Reteach

Speed of Crystallization Show photos and samples of igneous rocks with differing crystal sizes. Have students tell the relative rate of crystal formation—slow, fast, or very fast—and whether the sample formed near, beneath or above the surface.

[L2] [IS] **Visual-Spatial**

section 2 review

1. minerals and rock fragments
2. Large crystals indicate that cooling began slowly; the finer-grained background indicates that cooling sped up.
3. Gases expand as they rise, creating bubbles that burst at the surface, leaving a vesicular texture.
4. Because olivine crystallizes at high temperatures and quartz crystallizes at lower temperatures, by the time quartz crystals form, the olivine is already incorporated into solid rock. It is unlikely that both minerals will occur in the same rock.
5. Gabbro and basalt both contain low amounts of silica. Because basalt is a volcanic rock, you would find basaltic lava flows.
6. $5.3 \times 10^5 \text{ km}^3$

MA.B.1.4.1

Assessment

Oral Have each student prepare a quiz-show style answer for the category *Igneous Rocks*. Critique each answer and save the best ones for a game at the end of the chapter. [L2]

Sedimentary Rocks

1 Motivate

Bellringer

Section Focus Transparencies also are available on the Interactive Chalkboard CD-ROM.

L2 ELL

Section Focus Transparency Fossil Fascination

Most fossils are actually casts of animals or plants. When an animal dies and sinks to the sea floor, the body begins to decay and is buried under layers of sediment, such as mud or sand. These layers become rock, and the hard parts of the animal are replaced with minerals, such as iron pyrites or silica. These minerals then form the fossil. Usually, fossils show the hard parts of the animal or plant, such as shell or bones. Most fossils are found in sedimentary rocks—rocks that are created when shells or small loose bits of rock are laid down in layers. Examples of sedimentary rocks are limestone, sandstone, clay, and chalk.

1. Why do fossils usually show only the hard parts of animals or plants?
2. How can fossils help us learn about the past?
3. Where might you go in your area to hunt for fossils?

L2

Reading Preview

Tie to Prior Knowledge

Surface Igneous Rocks Have students recall that some igneous rocks, such as those from lava flows, form at the surface where they are exposed to wind, rain, and ice. L2

Frayer Model Have students divide a sheet of paper into quadrants. Instruct students to write a new vocabulary word in the center of the page. In the upper left, they should write the word's definition. In the upper right, they should list characteristics associated with the word. Have them record examples in the lower left and non-examples in the lower right.

Reading Guide

What You'll Learn

- **Explain** how and where sedimentary rocks form.
- **Discuss** how sedimentary rocks are used to interpret Earth's history.
- **Describe** how sedimentary rocks are classified.

Why It's Important

Knowledge of sedimentary rocks helps you understand where resources such as fossil fuels and groundwater come from.

Review Vocabulary

precipitate: an insoluble compound that comes out of solution during a chemical reaction

New Vocabulary

- clast
- porosity
- cementation

Figure 14 Rocks that are tumbled more than 3,000 km along the bottom of the Colorado River, shown below, can be broken into fine particles before they reach the Gulf of California.

Rocks from Surface Materials

Recall that rock is a consolidated mixture of minerals. Some of these minerals could be in bits and pieces of other rocks. Such small bits and pieces are called **clasts**. The word *clast* is from the Greek *klastos* which means “broken.”

Surface Attack What could reduce rocks of the crust to smaller sizes? Rocks inside Earth are protected from surface conditions. They are squeezed and heated and are reasonably stable under those physical conditions. In contrast, rock exposed at the surface is attacked by the weather. This action over a long time breaks rocks down into smaller-sized pieces and loosens them from their original positions. Loose chunks of rock, in turn, are attacked more easily by water and air, and are able to smash into each other. It is this slow, but constant smashing, grinding, and dissolving of clasts that can take place in rivers and streams, as shown in **Figure 14**, and in other environments.

Figure 15 Sandstone can form when sand grains are deposited, compacted, and cemented together.

Transportation and Deposition Mechanical weathering processes break rocks into smaller clasts, making it possible for the clasts to be eroded or removed from their original locations. When clasts are transported to new locations, they often become rounded before being deposited.

When clasts are loose on Earth's surface, they don't fit together perfectly. For example, a pile of baseballs will have plenty of space between the balls. This empty space is called **porosity**. Now imagine a pile of clasts, some rounded as they were transported by a river. Although smaller than the baseballs, the pile of clasts also will have some porosity. Sedimentary rock starts off with some porosity. When the clasts are clay minerals, which are sheet silicates that fit together tightly when compressed, porosity is minimal. It is in the porosity that water, oil, and natural gas are stored within Earth.

Buried Clasts Eventually, clasts can become consolidated into sedimentary rock. The making of clasts by weathering is a surface process, while the making of sedimentary rock occurs below the surface. What processes below the surface could hold clasts together tightly enough to make a rock?

When buried by more sediment deposited above them, clasts can be smashed together with such great force that they become compressed and stick together. The force is pressure created by gravity pulling down on all the material that overlies the clasts. Pressure increases the deeper in Earth that the clasts are, increasing the chance that the clasts will stick together. This process is called compaction.

Reading Check What force causes compaction?

Water moving between clasts carries dissolved minerals that can act as cement. Common minerals that are cement materials include quartz, calcite, hematite, and clay minerals. Under the right conditions these minerals slowly precipitate out of water and begin to fill spaces between clasts. This process is called **cementation**. Most of the time both compaction and cementation work together to make sedimentary rock. **Figure 15** shows how sedimentary rock becomes consolidated.

Reading Check

Answer gravity or compression

Quick Demo Modeling Concentration

Materials clean sand and/or gravel, clear-plastic cups, petroleum jelly, water-based glue.

Procedure Make a thin solution of glue and water. Coat the inside of the cup with a thin layer of petroleum jelly as a release agent.

Loosely fill the cup with the sand and/or gravel mix. Slowly pour the glue solution over the sediment mix. Set it aside to harden. Break away the cup and examine your synthetic rock. **L2 ELL**

Visual-Spatial

Teacher FYI

Cement is dehydrated limestone. Mortar is a mixture of varying amounts of sand and cement with water. When water is added, the cement rehydrates and an exothermic reaction starts. The end product of this reaction is a glue-like substance that binds the sand together. Concrete is similar to mortar, but gravel is

added to further increase the strength of the hardened product. It is sometimes mistaken for the sedimentary rock conglomerate because of its appearance. Concrete must cure for a long time to gain its full strength. Keeping mortar or concrete moist slows the hardening process and adds strength to the material.

Quick Demo

Sediment Settling

Materials Large, clear-plastic jar and lid, water, mixture of sand, gravel and clay (such as the clay on a baseball diamond).

Estimated Time 10 minutes or more

Procedure Fill the jar until it is half full of sediment mix and top it off with water. Cap the jar and shake vigorously. Set it down and allow the sediment to settle. The gravel will quickly settle out, but the water will remain murky for a long time, possibly days. In advance, ask what will happen; afterward, ask why the water remained cloudy. Ask for suggestions on how to measure the clarity of the water. **Very fine sediments take a long time to settle and the water must be completely still; possible suggestions may include shining a flashlight through the jar or trying to read or see an image through the jar.**

L2 ELL Visual-Spatial

Discussion

After the Quick Demo, engage students in a brainstorm setting to formulate a rule about settling rates for sediments and a rule for the vertical grain size distribution in a layer deposited by a flood. **L2**

Activity

Natural or Synthetic Have students compare and contrast a piece of broken concrete to a specimen of conglomerate. **Conglomerate is likely to have a wider variety of clast sizes and the cementing agent will be less well-distributed.** **L2**

ELL Visual-Spatial

Detrital Sedimentary Rocks

Detritus, from the Latin *deterere*, which means “to lessen or wear away,” is another name given to clasts. Sedimentary rocks that are made mostly of clasts are called detrital sedimentary rocks. Clasts can come in many sizes. In order of decreasing size, clasts are known as gravel, sand, silt, or clay. Most people use size names loosely, but to geologists, each size name has a specific meaning, as shown in **Figure 16**. These size names only tell the dimension of a particle, not its composition.

Detrital Sedimentary Rock Textures If someone asked you to define sand, what would you say? Some people might think sand is made only of quartz, or the common silica sand available in hardware stores. In fact, a sand-sized particle could be made of any kind of material. Some kinds of materials, such as quartz and feldspar, hold up better against the effects of weather than others, such as olivine and pyroxene, and are more common in sedimentary rocks.

Why would anyone care about the exact size of a clast? Geologists have found that size works well as a clue to the kind of environment in which a rock formed. One clast of gravel is large and heavy compared to one clast of sand. It takes more force, or energy, to lift or move gravel than it does to lift or move sand. The larger particles in a mix of clasts often can't be lifted by air or water, and instead bounce or scoot along Earth's surface. If you sampled a muddy river you might be surprised to find gravel or sand on the bottom of the river, but a jar of river

water might contain millions of tiny silt and clay particles. When water is calm, most clast sizes settle out. As water speeds up, the smallest clasts are lifted first, then larger clasts. During a flood, when the water is moving swiftly, all but the very largest particles are moved. The reverse happens as the water slows. Largest particles settle out first, followed by smaller particles.

Detrital Sedimentary Rocks		
Texture (grain size)	Sediment Name	Rock Name
Coarse (over 2mm)	Gravel (Rounded fragments) Gravel (Angular fragments)	Conglomerate Breccia
Medium (1/16 to 2 mm)	Sand	Sandstone
Fine (1/16 to 1/256 mm)	Mud	Siltstone
Very fine (less than 1/256 mm)	Mud	Shale

Figure 16 Sand is defined by size, not by composition. Sand doesn't even have to be made from rock material; it can be made from shells.

Differentiated Instruction

Visually Impaired Sedimentary rocks lend themselves to identification by touch because the rock name is determined by clast size. Provide visually impaired students with samples of siltstone, sandstone, and conglomerate to handle and compare.

L2 ELL Kinesthetic

 Reading Check

Answer Composition is dependent on what is available in the region and capable of being picked up by the transporting agent.

Fun Fact

Fun Fact Students might think that gold is the most valuable earth material. But the total value of all building aggregates (such as sand, gravel, cement and building stone) has a greater value than the amount of gold mined in a year.

Cementation In a homogenous solution, crystals can grow as material is added to the surface of existing crystals. However, imperfections on the crystal's surface can cause reorientation of crystal development. Also, changes in the composition or temperature of the solution can produce a layering effect. If enough material is available in solution, crystal growth can fill the space between grains of sediment and cement the grains together.

Cementation Though sedimentary rocks may form in arid, desert conditions or from compaction by glaciers, most sedimentary rocks are created from being deposited in water. Dissolved minerals in the water may precipitate onto the surfaces of the clastic particles and become the cement to hold grains of sand, silt and clay together. The minerals may also precipitate to form layered rock crystals as well. Make a supersaturated solution and allow the liquid to evaporate. Do the crystals form in layers?

Detrital Sedimentary Rock Compositions Detrital sedimentary rock composition depends on sources of rock material that were eroded, transported, and eventually deposited. Original rock material can be dislodged and carried by streams or water currents, blown by the wind, or rafted along by moving ice. The clasts can come from all the regions that these carriers moved over or through. The number of possible combinations of different kinds of clasts is large. However, the size of clasts is controlled by the ability of the carrier to move them.

Some minerals tend to be more common in detrital sediments because they are harder or more resistant to being dissolved. Quartz is such a mineral, which is why you might have thought clasts are always made of quartz. Geologists examine sedimentary rock compositions and try to reconstruct what happened to form them. You can try to reconstruct a sedimentary rock's history by imagining all the places that clasts could have come from and how they got there.

 Reading Check

What factors control the composition of a detrital sedimentary rock?

Detrital Rock Classification Just as igneous rocks are classified according to composition and texture, similar observations are used to classify detrital sedimentary rocks. Mineral composition is extremely variable, so adjectives are used to modify the general name of the rock. The general rock name is determined by clast size. The names of detrital sedimentary rocks are given in **Table 4**.

Clast size also provides clues to help determine the deposition environment of the sediment that formed the detrital rock. Suppose you have a sample of siltstone that contains shells of marine animals. You might conclude that the sediments were deposited in a shallow, calm area along the coast. The calm water allows small particles like silt to settle out. The shells give you a clue that the environment was near the ocean. Perhaps the sample also has fossils in the form of marine worm tubes. The fossils are traces of organisms that might have lived in soft mud.

Table 4 Common Clast Sizes Used to Name Sedimentary Rocks

Common Clast Size	Rock Name
Gravel or larger	Conglomerate
Sand	Sandstone
Silt	Siltstone
Clay	Shale

LAB DEMONSTRATION

Formation of Ripple Marks

Purpose Demonstrate how ripple marks indicate direction of water flow.

Materials pan, sand, electrical fan, spatula

Preparation Into the pan, pour sand to a depth of about 2.5 cm. Cover the sand with about 2.5 cm of water.

Procedure Use the fan to blow the water in one direction until ripple marks form. Have students describe the ripples. Smooth out the sand. Simulate wave action by moving the spatula back and forth in the water until ripple marks form. Have students describe the ripples.

Expected Outcome First set of ripples is asymmetrical; second set is symmetrical.

Assessment

What environmental conditions form each type of ripple? *asymmetrical—water or wind move in one direction; symmetrical—back-and-forth waves*

Mini LAB

Purpose Simulate the formation of evaporite rocks

Materials sauce pan, measuring spoons, two saucers, thermal mitts, stove, water, salt

Analysis

1. There will be a white crust in the saucer that contained water from the pan; the saucer that contained water from the lid will contain nothing.
2. The salt in the saucer is a crust of cubic crystals.

Assessment

Oral What position on the saucer had the greatest amount of crystal growth? **Outer edges should have the thickest growth.**

✓ Reading Check

Answer calcium carbonate; the hard parts of marine organisms

Reading Strategy

Find Supporting Details Have students start with the main idea: *There are three types of sedimentary rocks. Each type originates in a particular way.* Using this idea, students should find supporting examples and facts. Ask them to compose a paragraph incorporating the main idea and the supporting details.

Mini LAB

Modeling Evaporites

Procedure

1. Add to a **sauce pan** 1 L of **tap water** and 34 g (about 6 level teaspoons) of **salt** and stir with a **spoon**.
2. Place a **lid** on the pan and heat it on a **hotplate** to boiling. Droplets of a solution should be forming underneath the lid. This solution will be hot. Use **thermal mitts** to carefully remove the lid and drain off the liquid from the lid into a **saucer**. Replace the lid.
3. Repeat step 2 several times until you have several teaspoons worth of liquid from the lid.
4. Carefully pour enough of the pan's contents to half-fill a **second saucer**. Label each saucer to identify which water came from the lid and which came from the pan.
5. Allow both saucers to sit undisturbed until all of the water evaporates from each.

Analysis

1. What do you observe in the saucers after all of the water has evaporated?
2. Compare and contrast any substance you observe with some salt grains directly from the salt container. Use a magnifying lens to observe the substance in each saucer.

Chemical Sedimentary Rocks

Some sedimentary rocks form through the activity of chemicals dissolved in water. If the water contains more dissolved material than it can hold, then some of that dissolved material begins to form crystals that settle out of the water. These crystals build up to form new rock. There are two ways that this process gets started.

Precipitation If water receives more dissolved materials than it can hold in solution, then the excess must precipitate out as microscopic crystals. This crystallization of excess dissolved material is called precipitation. In a small percentage of limestones called oolites, calcium carbonate precipitates directly from sea water around preexisting particles, such as grains of silt or sand.

Evaporation The other option is for some water to evaporate. This leaves an oversupply of dissolved matter and again crystals are forced to form. Rock salt and rock gypsum are common chemical rocks formed in this way. They are often called evaporites because evaporation of water initiates their formation.

Biochemical Sedimentary Rocks

If sedimentary rocks contain the remains of living organisms they are called biochemical sedimentary rocks. Most of Earth's limestone is composed, at least partially, of the remains of marine organisms that had hard parts made of calcium carbonate. The shells of the organisms were cemented together by calcite mud. If you found a rock composed almost entirely of shells and shell fragments, you would have found limestone. Coquina is a variety of limestone that is formed mostly from broken shell fragments. The shells accumulated on the seafloor and were later cemented together with calcium carbonate. Most organisms whose shells contributed to the limestone-making process lived in warm, shallow seas. Animals without shells rarely contributed enough debris to make rock. More often, their soft remains deteriorated or were scavenged before they became part of a sedimentary rock.

✓ Reading Check

What chemical compound is limestone made of and where does it come from?

Another common rock that originates from the remains of organisms is coal. The starting material for coal is mostly plant matter. Coal is sedimentary rock composed almost entirely of the carbon that remains after plant material is compressed underground.

Figure 17 As sediment accumulates above a layer of peat, shown at the upper triangle, the peat becomes more compressed. Continual compression drives out water and other compounds, leaving behind a form of carbon called coal, shown at the lower triangle.

Coal usually develops from peat, a brown, lightweight deposit of moss and other plant matter. Shallow swamps or bogs in a temperate or tropical climate are likely environments of deposition. Partial decay of the plant matter uses up oxygen in the swamp water. This stops further decay and the remaining organic matter is preserved. Peat is transformed into coal largely by compaction after it has been buried by sediment.

Look at **Figure 17**. Coal goes through a series of changes as it forms from peat. Each stage of compaction drives out more impurities and leaves behind a more concentrated form of carbon. Coal often lies within repeated sequences of sandstone, shale, and limestone, which indicate alternating continental and marine conditions. This implies a low-lying environment near the sea, such as lagoons, large deltas, and swampy coastal plains. By studying coal fields, changes in Earth's climate, geological activity, and life forms may be traced and compared.

Post Reading

Cooperative Project Have groups of three students choose a particular sedimentary rock, such as conglomerate, to study. Ask them to develop a poster that describes these aspects of their rock: formation, composition, and common locations. Students also should include a picture of their rock type.

3 Assess

DAILY INTERVENTION

Check for Understanding
Sedimentary Rock Identification

Display several sedimentary rocks. To confirm an understanding of igneous rock classification, have students identify at least two criteria they can use to correctly identify each sample. **L1 ELL**

Visual-Spatial

Reteach

Remind students that sedimentary rocks are formed from sediments that have been cemented together. Show them a variety of sediments (gravel, sand, silt or clay, mud) and have students predict what type of rock would form if the sediments were cemented together. **L1 ELL**

Assessment

Content Have each student prepare a quiz-show style answer for the category *Sedimentary Rocks*. Critique each answer and save the best answers for a game at the end of the chapter. **L2**

section 3 review

Summary

Rocks from Surface Materials

- Sedimentary rocks have three main types that reflect their origins: Detrital, chemical, and biochemical.

Detrital Sedimentary Rocks

- Detrital sedimentary rocks can be composed of a wide variety of clasts.
- Clasts vary widely in size.
- Many possible combinations of clast composition and clast size produce a large number of detrital sedimentary rocks.

Chemical Sedimentary Rocks

- Chemical sedimentary rocks form as minerals precipitate from water rich in dissolved mineral matter.

Biochemical Sedimentary Rocks

- Biochemical sedimentary rocks form from the remains of organisms.

Self Check

- Describe** the requirements for a material to be classified as a sedimentary rock.
- Compare and contrast** the formation of an evaporite rock to one of detrital origin.
- Explain** how clast size affects transportation of different-sized clasts. Also, explain the order in which different-sized clasts are deposited.
- Think Critically** Suppose a stream floods over its banks. If you dug a hole through the layers of sediment deposited near the edge of the channel after the water receded, what would you likely see?

Applying Math

- Calculating Sedimentation Rate** Imagine that thin layers of sediment are being added to a lake that is 10 m deep. Suppose the average yearly influx of sediment is 2.5 mm. About how long would it take to fill in the lake with sediment?

section 3 review

- compacted and/or cemented mixture of minerals and/or rock fragments (or plant matter in coal)
- Both rocks are sedimentary and form in water environments. Detrital—composed of sediment cemented together, variety of minerals, individual grains can be seen; evaporite—forms when water evaporates leaving minerals behind, crystalline texture, one mineral, generally one color.
- Large clasts require faster-moving water or wind to be lifted and transported; they are the first to be dropped as the water or wind slows down.
- You would find layers of sediment with the largest clast sizes in the bottom layers and progressively smaller clast sizes upward.
- assuming no sinking or settling occurs on the lake bottom—4,000 years

L2 ELL

Section Focus Transparency **Marvelous Marble** **Chapter 20**

Marble is a metamorphic rock that is frequently used in sculpture and architecture because of its beauty. It is finely grained and dense, with a nondirectional structure. It is capable of taking a high polish and is often irregularly veined and colored by impurities. White marble has been quarried in Greece, Italy, Turkey, India, China, and the United States. Among the most renowned sources have been the quarries of Carrara in the Apuan Alps of Italy. Confusingly, the name "marble" is sometimes used to refer to any stone that takes a polish, although such stones may also include alabasters, granites, and serpentines. Many of the world's great structures, such as the Lincoln Memorial, are made of marble.

1. Why might marble be veined or colored with impurities?
2. Name a marble building or structure in or near where you live.
3. What is a common sedimentary rock that is also popular as a building material?

L2

Reading Preview

What You'll Learn

- **Identify** physical conditions that cause metamorphism.
- **Explain** where metamorphism occurs.
- **Classify** metamorphic rocks.

Why It's Important

An awareness of change leads to an improved ability to adapt to change.

Review Vocabulary

chemical reaction: process in which one or more substances are changed into new substances

New Vocabulary

- foliated
- rock cycle

Metamorphic Rocks

In the last section you learned that sedimentary rocks show great variety with many different combinations of composition and texture. The same is true for metamorphic rocks. Metamorphic rocks, like the one shown in **Figure 18**, are rocks that have been changed by some combination of thermal energy, pressure, and chemical activity. As these agents begin to act on a preexisting rock, its atoms rearrange and sometimes form new minerals. The word metamorphic comes from two stems, "meta" (to change) and "morph" (form). Any igneous, sedimentary, or metamorphic rock is subject to change through metamorphism.

Conditions that form metamorphic rocks are somewhere between the sedimentary and igneous environments. In other words, consolidation of sediment to form sedimentary rock occurs at lower pressures and temperatures than typical metamorphic conditions. On the other hand, igneous rock formation requires rock to melt and solidify. Igneous processes operate at higher temperatures than metamorphism which occurs while rock remains solid.

Figure 18 Sharp folds sometimes display intense transformations in metamorphic rocks.

Metamorphic Rock Composition

The agents of metamorphism are thermal energy, pressure, and chemical activity. Water and carbon dioxide are common active chemicals that exist as a fluid and chemically react with rock. This fluid can come from molecular water or carbonate locked in the rock itself, or can be introduced from a nearby intrusion of magma.

What are three causal agents of metamorphism?

Changing Minerals Clay minerals, micas, and amphiboles are examples of minerals that contain water in their crystal structures. Clay minerals tend to form micas with increasing metamorphic conditions. If metamorphic conditions of pressure and temperature continue to increase, the water can be driven away completely. Minerals, such as garnet, that contain some of the same elements found in clays (aluminum and silicon) can result. In this way, some new minerals form by dehydration at higher temperature and pressure.

Environments of Metamorphism So, what's causing these changes? Deep burial or regional movements of large parts of Earth's crust and uppermost mantle are possible causes. These large-scale changes, called regional metamorphism, produce huge areas of changed rock. Another smaller-scale cause is local contact of any preexisting rock with magma. This is called contact metamorphism. You produce contact metamorphism when you place food in a hot pan coated with oil and it quickly begins to burn. One important difference is that in cooking, chemical reactions take place rapidly, while metamorphic changes occur over thousands or millions of years.

Metamorphic Rock Textures

Metamorphic processes create many rock textures, but a few general types can help you understand the processes that formed them. **Foliated** textures in metamorphic rocks have lots of layers or bands. Nonfoliated metamorphic textures include rocks whose grains are in more random orientations. Some nonfoliated textures resemble igneous rock textures, in which grains are locked tightly together. **Figure 19** shows examples of these textures.

Figure 19 *Folio* means "leaf."

Foliated texture has the appearance of layered leaves or pages of a book. The texture of the first metamorphic rock shown below is foliated; the second is nonfoliated.

Reading Check

Answer thermal energy, pressure, chemical activity

Content Background

Water is the most important fluid involved in metamorphism. Water is thought to affect metamorphic chemical reactions by dissolving mineral ions and carrying them to other locations where they react with other mineral ions. Ask students where they think the water might come from in metamorphic rock. **Some water is subducted along with sediment at convergent plate boundaries. Water also might come from the molecular structure of some minerals or magma.**

Discussion

Metamorphism Place time frames on the process of metamorphism. Ask students how long they think these changes take. What are the variables?

Responses will vary, but all the time frames should range from millions to billions of years. Variables include depth of burial, heat sources, additional heat from Earth's interior or tectonism, presence or absence of fluids. **L2 ELL LS**

Materials large hand specimens of slate, phyllite, schist, gneiss, marble, and quartzite

Estimated Time 15 minutes

Procedure Use the hand samples to reinforce the distinction between foliated and non-foliated textures and to show the progressive degree of metamorphism from slate to gneiss. **L2**

ELL LS Visual-Spatial

Visual Learning

Figure 18 What can you observe about the rock in this figure that indicates it is not sedimentary? **Sedimentary rocks display layering, but these layers are distorted just as they are in metamorphic rocks. Some layers also show signs of stress by thinning and thickening in the folds.**

L2 ELL LS

Differentiated Instruction

Learning Disabled Identification of metamorphic rocks relies on visual characteristics. Provide several sets of metamorphic rocks that show the gradation from slate to gneiss. Help the students recognize the physical changes as they examine the samples from lowest degree of metamorphism to highest degree. **L1 ELL**

✓ Reading Check

Answer Grains align perpendicular to the direction of compression.

Discussion

Index Minerals Using the information in the content background below, introduce students to the concept of index minerals. Obtain a map showing their distribution to help illustrate the concept. In order of decreasing temperature, the minerals are: sillimanite, and alusite and staurolite/kyanite, garnet, biotite and chlorite. Ask students to compare and contrast the use of index minerals to the use of index fossils. **Both occur in specific areas; minerals in an area that experienced a specific temperature, fossils in rocks that represent a specific period of time. Their occurrence in rocks can be used to fine-tune an interpretation of the rock body they occur in.**

Teacher FYI

Mapping and Metamorphic Minerals

Contact metamorphism can result in the formation of a new assemblage of minerals. Research has determined the temperature ranges under which certain minerals form. These minerals are called index minerals. They form over a narrow range of temperature and can be used to characterize a particular degree of metamorphism. When an igneous intrusion occurs, the temperature is hottest closest to the intrusion and decreases farther away. The minerals that form as a result of this contact metamorphism record the change in temperature away from the intrusion. The location of the intrusive igneous body can be located by mapping the occurrence of index minerals and following the apparent increase in temperature.

Figure 20 Direction of applied force affects orientation of mineral grains.

- A** Mineral grains are randomly oriented when no directed force is involved.
- B** Orientation of mineral grains is perpendicular to the direction of pressure caused by compression.
- C** Mineral grains are parallel to the direction of shearing force.

ScienceOnline

Topic: Metamorphic Rock Textures

Visit fl.gpscience.com for Web links to information about metamorphic rock textures.

Activity: Select from metamorphic microtextures: Gneiss, marble and foliation. Make a detailed colored sketch of each of the photomicrographs showing these textures. Label your drawings.

Foliated Rocks The most common sedimentary rocks in Earth's crust are mudrocks such as shale and siltstone. These rocks contain abundant clay minerals, and when metamorphosed, the clays change to minerals in the mica group, such as muscovite. The mica group minerals also change in grain size with increasing degrees of metamorphism.

When squeezed and heated, layers of mica line up in a direction that is perpendicular to the direction of compression or parallel to the direction of shearing, as shown in **Figure 20**. For example, slate is a fine-grained, foliated metamorphic rock that splits easily along flat, parallel planes. It typically formed when shale was compressed, causing mica grains to orient perpendicular to the compression.

✓ Reading Check

How does compression affect the orientation of mica grains in metamorphic rocks?

Sometimes it's easiest to consider foliated rocks as a progression of increasing metamorphic conditions. The smallest-grain sizes in foliated textures occur in slate, which forms thin layers and exhibits rock cleavage. The rock cleavage comes from the parallel alignment of mineral grains within the rock. If the metamorphic conditions increase, some of the mineral grains in the slate grow and produce phyllite. With continued grain growth, a shiny mass of mica sheets called schist (SHIHST) forms. Finally, at the highest level of change a rock called gneiss (NISE) is produced. Gneiss rock textures often are banded, and gneisses generally represent the limit between metamorphic and igneous conditions.

Nonfoliated Rocks Similar in texture to intrusive igneous rocks, nonfoliated metamorphic rocks tend to have random crystal orientation and uniform grain size. In general, mineral grains tend to grow as the grade of metamorphism increases. Imagine a limestone with microscopic grains. Under the influence of thermal energy, pressure, and fluids, such a limestone recrystallizes in large beautiful grains of calcite that are readily visible in a hand specimen. This resulting rock is marble, and it is essentially chemically equivalent to the limestone.

Metamorphic Rock Classification

Much like other rock types, metamorphic rocks can be classified based on texture and composition. Beginning with texture, you can determine whether a metamorphic rock is foliated or nonfoliated. Remember that in any classification, there are exceptions, as illustrated in **Figure 21**.

Cultural Diversity

Have the students research the use of Earth materials in the construction of housing in different regions on Earth.

✓ Active Reading

Learning Journal Have students divide a sheet of paper in half and record research notes, lecture notes, or vocabulary terms in the left column. In the right column, they respond to, interpret, question, or analyze the left column entries. Students can write a Learning Journal while reading about metamorphic rock.

Figure 21

Earth materials undergo change, even when buried far below the surface. Deep in the crust, high temperature and pressure conditions alter the chemical composition and structure of rocks in predictable ways over time, producing metamorphic rocks. Metamorphism, however, also can occur rapidly, violently, and without warning.

Scientists estimate that the force created by a meteorite impact could be nine million times greater than atmospheric pressure. This type of collision would send enormous shock waves throughout surrounding rock strata, rearranging atoms into new crystal structures stable at higher temperature, and pressure conditions.

Large meteorite impacts leave scars that can remain visible for millions of years. Taken from the space shuttle, this image shows the *International Space Station* above the Manicouagan impact crater in Quebec, Canada. The meteorite that created this crater struck Earth 214 million years ago, hurling debris high into the atmosphere and leaving evidence in the rock record worldwide.

With a diameter of 100 km, the Manicouagan crater is one of the largest impact structures preserved on Earth. The force of the collision caused rock melting and rock metamorphism to a depth of about 9 km. Mineral grains in metamorphic rocks at the site are deformed extensively, evidence that an intense compression wave shocked the strata.

SECTION 4 Metamorphic Rocks and the Rock Cycle **633**

Visualizing Shock Metamorphic Rocks

Have students examine the pictures. Then provide them with the following information and ask them to provide their own explanations.

Most of the rock found at the center of the Manicouagan impact crater is either igneous or metamorphic rock. Explain the presence of igneous rock at this location. *Possible answer:* The force of the meteorite impact resulted in the release of a tremendous amount of heat energy. High temperatures in the rock strata caused some material to melt. As the molten material cooled and hardened, igneous rock was formed.

In 2002, geologists published the discovery of a 2-cm layer of impact material in the rock strata in western England. Based on the decay of radioactive potassium, the debris layer was dated at 214 million years old and tied to the formation of the Manicouagan impact crater. Explain how material from Canada made its way into rock strata in England. *Possible answer:* The meteorite struck with such force that debris was ejected far into the atmosphere, then carried away from the impact site by various atmospheric processes. Eventually, heavy materials settled back to Earth, creating a layer in the rock strata in certain locations.

Activity

Manicouagan Imagine that you viewed the Manicouagan meteorite impact from a safe distance 214 million years ago. Write a description of what you saw and heard before, during, and after the collision. Share your observations with other classmates.

Teacher FYI

Rock Cycle Activity In the rock cycle, volcanic activity occurs fastest, while cooling of igneous intrusions and the heat and pressure of metamorphism occurs slowest. The processes of erosion, transport, and deposition all can be interrupted by new episodes of uplift and erosion. This recycling is possible until sediments reach the deep ocean floor. Metamorphic rocks also can be recycled through mountain-building processes.

Discussion

Have students speculate about what rocks would look like if there were three lava flows of a gas-rich lava, one atop another. *It would look like a layer cake; a glassy layer (cake) with a frothy layer atop it (icing), then glass, froth, glass, and froth on top.*

L2 ELL IS Visual-Spatial

What would happen if all weathering processes stopped? *Without weathering, the cycle would not continue.*

L2

Reading Strategy

Brainstorm Post four large sheets of paper. Each should have one of the following headings: *Weathering Rock Composition, Texture, Classification, or The Rock Cycle*. Form four student groups—one for each topic. Students will have three minutes to brainstorm and record ideas that fit their category. Groups rotate to other topics until all have visited each one.

Mineral Composition Next, consider the mineral composition. Mineral composition provides clues about the original rock type before metamorphism, and also indicates to what degree a rock has been metamorphosed. The original rock material, often called the parent rock, and the conditions of metamorphism together control the resulting metamorphic rock. So, in studying rocks from the field, geologists must work backwards. Field samples are the results of many geologic conditions, most of which cannot be accurately reproduced in the laboratory. Some conditions have been reproduced, however, and scientists can use mineral composition to estimate the pressure, temperature, and chemical activity that resulted in the formation of a metamorphic rock.

The Rock Cycle

Illustrations often simplify complex ideas. A diagram of the rock cycle, shown in **Figure 22**, summarizes processes that you have learned about in this chapter. Processes of the **rock cycle** include any chemical and physical conditions that continuously form and change rocks. Notice that some processes happen at Earth's surface, while others happen deep below the surface.

Figure 22 The rock cycle is a continual process in which rocks change from one form to another.

LAB DEMONSTRATION

Purpose Review the rock cycle.

Materials: rock specimens of the rock cycle; 3 ring stands with rings; 3-in × 5-in cards (7); jumbo paper clips, hole punch; large rubber bands; hole reinforcers

Preparation Label the cards *crystallization, erosion, transportation, deposition, burial, increase in heat and temperature, and recrystal-*

lization. Punch a hole at each end of a card and reinforce. Connect two jumbo clips to a rubber band. Attach a clip to each end of a card.

Procedure Place a rock on a ring. Use an action card to connect the ring to another ring. Continue the process until a rock cycle is constructed.

Expected Outcome Students should be able to model the rock cycle.

Assessment

What would happen if all weathering processes stopped? *Without weathering, the cycle would not continue.* L2

As rock material moves through stages of the cycle, all matter is conserved. Minerals from granite are found in the sediments that were eroded from those igneous rocks. Those same minerals could be present in sedimentary rocks formed later. Atoms that have been mobilized during weathering or metamorphic chemical reactions are not destroyed, but can end up as dissolved materials in solutions. Mineral crystals later can precipitate from those solutions. The atoms are never destroyed, only rearranged into new forms that are stable under the present conditions.

Also note that many different paths, indicated by arrows in **Figure 22**, can be taken by rock material as it changes within the cycle. Understand that these processes may take long periods of time, occurring over millions of years. Other processes happen suddenly, such as an erupting volcano, but this does not change the fact that there is no beginning and no end to the rock cycle.

 **Reading Check** Describe several examples of how matter is conserved in the rock cycle.

section 4 review

Summary

Metamorphic Rocks

- Metamorphic rocks can form from any preexisting rocks.

Metamorphic Rock Composition

- Agents of metamorphism can cause new textures and new minerals to form.

Metamorphic Rock Textures

- Metamorphic rocks are foliated or non-foliated.
- As metamorphic conditions increase in magnitude, mineral grains may grow larger.

Metamorphic Rock Classification

- Metamorphic rocks are classified based on mineral composition and texture.
- As with all rock classifications, some metamorphic rocks are exceptional and not easily categorized.

The Rock Cycle

- Although rocks are subject to many changes, matter is conserved through processes of the rock cycle.

Self Check

- Explain** the requirements for a material to be called a metamorphic rock.
- Compare and contrast** foliated and non-foliated textures.
- List** the following sedimentary rocks: limestone and shale. Provide the respective common names of the metamorphic rocks that each one becomes.
- Identify** which rock in question 3 is foliated.
- Critical Thinking** A marble contains occasional layers of the mineral muscovite. What possible parent rock composition could have been metamorphosed to produce this rock?

Applying Math

- Calculate Mass** Suppose a sculptor wants to use marble with an average density of about 2.7 g/cm^3 . The block of marble is one meter on every side. What is the mass of the block? If the sculptor knows from experience that the finished product will only use 45% of the block, and the rest is waste, then what will the mass of the statue be?

More Section Review fl.gpscience.com

SECTION 4 Metamorphic Rocks and the Rock Cycle 635

section 4 review

- The rock must show evidence of the effects of heat, pressure, and/or chemical activity such as foliation, increased crystal size, or new minerals.
- Both form from an increase in heat and pressure. They also show a change in mineral composition and grain size. Foliated—ranges from faint compact layering and uniform color to distinct light and dark bands with visible crystals of uneven sizes; non-foliated—mostly monomineralic, one color, crystals uniform in size, blocky in shape
- limestone to marble; shale to slate
- slate
- alternating layers of shale (muscovite) and limestone (marble)
- Density of marble = 2.7 g/cm^3 ; $1 \text{ m}^3 \text{ block} = 1 \text{ million cm}^3$; $1 \text{ million cm}^3 \times 2.7 \text{ g/cm}^3 = 2.7 \times 10^6 \text{ g}$; the statue weighs $1.215 \times 10^6 \text{ g}$

 **MA.B.1.4.1**

Reading Check

Answer Minerals can be eroded from granite and incorporated into sedimentary rock and minerals from sedimentary rock can be dissolved and precipitate as different minerals.

Post Reading

Article Ask students to imagine that they are writing an article for a geology journal about their discovery of metamorphic rocks in an old mine. Ask them to include information about the type of metamorphic rock and its mineral composition, texture, and method of formation. Make a booklet of all the articles.

3 Assess

DAILY INTERVENTION

Check for Understanding

Metamorphic Textures

Display several metamorphic rocks. Have students state at least two criteria they can use to correctly identify each sample. **L2**

Reteach

Demonstrate how foliation develops perpendicular to the direction of pressure. Knead a ball of clay until it is soft. Add some uncooked, long-grained rice and knead the clay until the grains are randomly scattered. Place the clay ball on the table. Slowly and firmly, apply pressure to the top of it. When the ball is about half its original height, cut it in half. Students will observe that the rice grains are now aligned, as in foliation. **L1 ELL AS Visual-Spatial**

Assessment

Content Have each student prepare a quiz-show style answer for the category *Metamorphic Rocks*. Critique each answer and save the best answers for a game at the end of the chapter. **L2**

SECTION 4 Metamorphic Rocks 635

Real-World Problem

Purpose Students will gain experience in observation, classification, and use of a classification key.

Process Skills observe, evaluate, interpret data, record, collect data

Time Required Three 40-minute sessions

Safety Precautions

- Damage to clothing from sharp objects and chemicals is possible.
- Dilute/hydrochloric acid—5%

Procedure

Teaching Strategy

- Identify rocks from one major rock group during each session.
- Give each lab group pairs of rocks and limit their time (5 min) to observe and record data. When time is up, rotate the rocks to the next group.
- If time allows, during the third session, provide samples from the first two sessions for comparison.

Troubleshooting

Have one or two acid test stations, which you monitor closely. Do not give every group acid. Stress that only ONE drop of acid is necessary and the sample must be blotted dry with paper towel after the test.

Goals

- **Observe** physical properties of minerals in rocks to determine their compositions.
- **Classify** each rock according to general type: Igneous, sedimentary, or metamorphic.
- **Identify** each rock based on its composition and texture.

Materials

rock samples
nail
penny (pre-1986)
magnifying lens or particle size chart
dilute HCl
paper towels
glass plate
* binocular microscope
unglazed porcelain tile
Resource Handbook, "Rocks"

**Alternate material*

Safety Precautions

Identifying Rocks

Real-World Problem

You've learned to identify most everything around you. This is an automatic process most of the time. You learned by repetition and by asking what things are called. By the time you were five years old you could name many different kinds of objects. You could identify the people in your life. You might not have had the same experience in identifying rocks—at least not yet. In this lab, you will identify rocks using a more formal approach. How can you determine the composition and texture of common rocks? What can a rock's composition and texture indicate to you about how it was formed?

Procedure

1. Construct a horizontal data table with ten columns and four rows.
2. Label the tops of columns 1 through 10, in the top row, as follows:
 - 1) Sample number
 - 2) General rock type (igneous, sedimentary, metamorphic)
 - 3) Crystals (yes/no)
 - 4) Grain size (large/small/none)
 - 5) Gas-bubble holes (yes/no)
 - 6) Fossils (yes/no)
 - 7) Particle size (gravel/sand/silt/clay)
 - 8) Foliations (yes/no)
 - 9) Additional observations
 - 10) Rock name

Alternative Inquiry Lab

Rocks from Home Many students collect rocks. They can be encouraged to bring some rocks from home to be evaluated during this lab. Many of these rocks have novel characteristics, such as an attractive color, unusual shape or texture, fossils, petrification, etc. Be aware that sometimes these items are not rocks. Byproducts from industrial processes, such as slag, often are

mistaken for rocks. Knowing where a rock was found can be important when learning about rocks.

Using Scientific Methods

- Obtain three rocks provided by your teacher.
- Observe** each rock. First, try to determine if it is igneous, sedimentary, or metamorphic. Then record everything else you observe. Your data table columns will serve as a checklist to help organize your observations.

WARNING: If you choose to use the acid test for calcite identification, use only one drop of HCl. A positive reaction to acid is the presence of tiny bubbles rising through the drop. Blot the liquid off the sample with a paper towel before leaving it. Be careful to keep acid away from skin and clothing.

- Identify** the rock with the help of Resource Handbook, "Rocks," at the back of your textbook.
- Repeat** steps 4 and 5 to check that your results are replicated. Keep an open mind.

Analyze Your Data

- Identify** the texture observations that helped you distinguish igneous rocks from sedimentary rocks.
- Determine** which rock samples required the fewest tests to identify them and explain why.

Conclude and Apply

- Evaluate** rocks according to difficulty for identifying and classifying.
- Explain** which observations were useful for the largest number of rock samples.
- Evaluate** your data table in terms of including important observations. Explain whether there were any observations you left out of your data table that are critical for distinguishing rocks.

Communicating Your Data

Present your findings to the class. Discuss any observations that were different from those of your classmates. Discuss the column headings you included in your data table and defend your choices.

LAB 637

Analyze Your Data

- igneous rocks—interlocking crystals, polymineralic (many minerals); sedimentary rocks—individual grains cemented together, some are layered, some contain fossils, generally uniform in color
- Answers will vary. Rocks that have distinguishing characteristics will be easy to identify; granite—large crystals and generally light colored, some limestones have fossils and all react to acid

Expected Outcome At the very least, students should be able to accurately group specimens into the three main rock categories and name at least two rocks in each category.

Error Analysis Have students compare results with others to discover common errors.

Conclude and Apply

- Answers will vary. Students may mention grain size, mineral composition and special features such as foliation.
- Texture patterns should rank high as most useful, such as grain size, clast size, foliation, or banding. General color may be also ranked as useful.
- Answers will vary. Students may point out the specialized characteristics that only a few rocks may exhibit; such as acid reaction or feel (rough or slick).

Assessment

Oral Ask students to differentiate between those rock characteristics that allowed them to sort the specimens into the three main rock categories and those characteristics that allowed for identifying the rock. [L2]

Communicating Your Data

Have students compare experiences in identifying the specimens and develop a flowchart of strategies or procedures for speeding up the identification process.

Content Background

Kaolinite, $\text{Al}_2\text{Si}_2\text{O}_5(\text{OH})_4$, is one of the most important minerals found in clay. Because kaolinite crystals occur in interlocking layers, little water can penetrate the mineral. This prevents materials made from kaolinite from swelling in the presence of liquids or expanding when heated. The absence of water also makes ceramic materials very heat-resistant.

Kaolinite is one of the most common minerals on Earth. It is a weathering product of the mineral feldspar. It is stable only under conditions of low temperature and pressure such as those present at Earth's surface. Deposits of kaolinite often are formed through the weathering of granite and other rocks that are rich in feldspar. In the United States, major deposits are mined in Georgia, North Carolina, and Pennsylvania.

Discussion

What's your opinion? Imagine that a large company is planning to mine kaolinite in your area. How would local residents feel about a kaolinite mining operation being established near the schools, homes, and farms? Possible answer: Kaolinite is not a radioactive or otherwise dangerous mineral. Positive effects for the local economy are likely. However, any type of mining operation raises environmental and safety concerns, including surface water contamination, landscape and habitat destruction, dust generation, and noise pollution, among others. [L2]

Investigate the Issue

Kaolinite Mines in the United States Have student groups research the location of kaolinite mining operations in the United States, and then plot locations on a U.S. map. [L2] **ELL**

Earth Materials at Work

What is clay, and where does it come from?

What do a commode, a brick, and a coffee mug have in common? While these items have widely different uses, they share an important component—a material called clay. Clay is found in many locations worldwide. Because of its unique properties and availability, clay has been used by civilizations throughout history to make items including building materials, pottery, and tablets for recording information.

Clay forms through weathering, crystallization, and deposition of Earth materials. The

word *clay* really represents an entire group of many different minerals. These minerals have particles with a diameter of 0.004 mm or less. When wet, most

Clay minerals are used to make many items of pottery and dinnerware.

clay minerals can be molded into a variety of shapes. When water is driven off under high temperature conditions, the material may become as hard as stone.

Clay deposits typically are found in sedimentary rock layers close to Earth's surface. As a result, clay mines are generally shallow, with depths of less than 150 m. Companies in the United States often reclaim the landscape that they mine. First, the topsoil and uppermost clay layer are removed and stored at another location. After clay is mined from an area, leftover Earth materials are returned to the pit. This layer is covered with topsoil, into which vegetation is planted.

Ceramic materials have diverse applications in manufacturing, building, art, and everyday life. Products made from clay minerals include floor tiles, fine china, and dental porcelain. The import, export, and use of clay materials contribute significantly to the world economy.

Kaolinite, a type of clay, is a common mineral on Earth.

Brainstorm Ceramic products can be found at school, at home, and in stores. Make a list of ceramic products that you encounter or use on a regular basis.

Brainstorm Students should be able to identify many items made from ceramic materials such as pottery, bricks, cement, floor and wall tiles, sinks, bathtubs, planters, fine porcelain, table ware, sewer pipes, and many others. Remind students that the unique properties of the clay which forms these materials enables them to withstand high temperatures and resist liquid infiltration. [L3]

Resources for Teachers and Students

Mineral Information Institute, 501 Violet Street, Golden, Colorado, 80401

A Field Guide to Rocks and Minerals (Peterson Field Guides), Frederick H. Pough and Roger Tory Peterson, Houghton Mifflin Company, 1998

Reviewing Main Ideas

Section 1 Minerals

1. Only eight elements compose more than 98 percent, by mass, of Earth's crust.
2. Minerals are naturally occurring, inorganic solids that have a crystalline structure and predictable chemical composition.
3. Major mineral groups that form the bulk of Earth's crust are known as the rock-forming minerals.
4. Every mineral has characteristic physical properties that help in its identification.

Section 2 Igneous Rocks

1. Igneous rocks must form from solidification of magma or lava.
2. Igneous rocks can be separated into two categories: Intrusive—those that form in Earth—and extrusive—those that form at Earth's surface.
3. Igneous rocks are classified based on their texture and composition.
4. Igneous rocks with granite-like compositions are associated with continental crust, while igneous rocks with basalt-like compositions are associated with oceanic crust.

Section 3 Sedimentary Rocks

1. Sedimentary rocks are consolidated mixtures of minerals, rock fragments, organic debris, or other natural materials.
2. Sedimentary rocks can contain or be made entirely of the remains of organisms.
3. Detrital sedimentary rocks form through the processes of cementation and compaction.
4. Sedimentary rocks are classified based on clast size and composition.

Section 4 Metamorphic Rocks and the Rock Cycle

1. Metamorphic rocks are made through the effects of heat, pressure, and chemical activity on preexisting rocks.
2. Metamorphic rocks can be divided into two categories: Foliated—having layers or bands—and nonfoliated—with grains in random orientations.
3. Parent rock material and conditions of metamorphism control the composition of a metamorphic rock.
4. The rock cycle describes all processes in Earth that continuously change Earth materials.

FOLDABLES™ Use the Foldable that you made at the beginning of this chapter to help you review Earth materials.

Match the correct vocabulary terms with each description below.

1. molten rock
2. grain size and arrangement
3. coarse grained
4. scratch resistance
5. uneven break
6. consolidated minerals
7. particle of rock
8. layers or bands
9. empty space
10. fills porosity
11. planar break
12. natural, inorganic, crystalline solid

Checking Concepts

Choose the word or phase that best answers the question.

13. What is the most common group of minerals?
 - A) carbonates
 - B) silicates
 - C) sulfates
 - D) oxides

14. What is a factor that controls grain size in igneous rocks?
 - A) porosity
 - B) cleavage
 - C) cooling rate
 - D) temperature
15. What do all the silicate minerals have?
 - A) the same hardness
 - B) the same crystal structure
 - C) silicon and oxygen
 - D) silicon and carbon as common elements
16. Through what process does chemical sedimentary rock usually form?
 - A) cementation of sand
 - B) compaction of clasts
 - C) evaporation of melt
 - D) precipitation of crystals
17. Which of the following features are extrusive igneous rocks least likely to have?
 - A) fossils
 - B) small grains
 - C) vesicular texture
 - D) porphyritic texture

Use the photo below to answer question 18.

18. Which of the following descriptions best describes the large-grained igneous rock shown above?
 - A) extrusive and basaltic
 - B) extrusive and granitic
 - C) intrusive and basaltic
 - D) intrusive and granitic

Use the ExamView® Pro Test Bank CD-ROM to:

- create multiple versions of tests
- create modified tests with one mouse click for inclusion students
- edit existing questions and add your own questions
- build tests aligned with state standards using built-in State Curriculum Tags
- change English tests to Spanish with one mouse click and vice versa

Interpreting Graphics

19. Copy and complete the concept map on igneous rocks.

20. Copy the following table on a separate sheet of paper. Use Bowen's reaction series to fill in the blanks.

Crystallization Temperature Ranges for Mineral 1 and Mineral 2

Temperature Range	Mineral 1	Mineral 2	Rock Name
Low	mica	quartz or K-feldspar	granite or rhyolite
Intermediate/High	pyroxene	calcium plagioclase	gabbro or basalt

Thinking Critically

21. Explain how cooling rate affects the texture of an igneous rock.
22. List the characteristics that help you identify sedimentary rocks.

23. Determine the identity of each rock from the following descriptions.
- quartz-rich, coarse interlocking grains, with noticeable amounts of potassium feldspar
 - foliated mass of mica group minerals with some garnet
 - nearly pure mass of fossil shells cemented by calcite
 - dense black, fine-grained, with some gas bubble holes
 - light colored, very low density, frothy (vesicular), glassy

Use the photo below to answer question 24.

24. Describe the kind of force and the direction it was most likely applied to produce this foliated metamorphic rock.

Applying Math

25. If a miner were extracting rock that contained 0.015% gold by mass, how many kilograms of rock must be processed to obtain one kilogram of gold?
26. The body of ore described in question 25 is estimated to have an average density of 6.0 g/cm^3 and contain $1.5 \times 10^5 \text{ m}^3$ of ore. How many kilograms of gold potentially could come from this body of ore?

Interpreting Graphics

19. See student page.
20. See student page.

Thinking Critically

21. the faster the rate of cooling, the smaller the crystals
22. presence of clasts and/or fossil, evidence of cementation and/or porosity
23. a. granite
b. schist
c. limestone
d. vesicular basalt
e. pumice
24. Compression was perpendicular to the foliation

Multiple Choice

1. B
2. A
3. B
4. B
5. C
6. C
7. A

Gridded Response

8. 5.5 times more
9. C is calcium (14.0% of 25.7 is 3.6% of 100); E is potassium (10.1% of 25.7 is 2.6% of 100)

Record your answers on the answer sheet provided by your teacher or on a sheet of paper.
The assessed Florida Benchmark appears above the question.

Multiple Choice

1. Which is the most common element in Earth's crust?
 - A. aluminum
 - B. oxygen
 - C. potassium
 - D. silicon

Use the image below to answer question 2.

2. Which property of a mineral, used in its identification, is shown?
 - A. cleavage
 - B. fracture
 - C. hardness
 - D. luster
3. Which is a measure of a mineral's resistance to scratching?
 - A. cleavage
 - B. hardness
 - C. luster
 - D. streak

4. Why is graphite used in the core of some pencils?
 - A. Its hardness is high enough to leave a scratch on paper.
 - B. Its hardness is low enough to leave a streak on paper.
 - C. Its metallic luster gives it a dark color.
 - D. Its metallic luster makes it shine on paper.
5. Which mineral is very important to the production of machinery for manufacturing goods?
 - A. feldspar
 - B. halite
 - C. hematite
 - D. quartz

Use the photo below to answer question 6.

6. The formation of which type of rock produced the rock feature shown above?
 - A. foliated metamorphic rock
 - B. extrusive igneous rock
 - C. intrusive igneous rock
 - D. nonfoliated metamorphic rock

7. Which is a dark-colored igneous rock with small grains?

- A. basalt
- B. gabbro
- C. granite
- D. rhyolite

Gridded Response

8. If the percent by mass of silicon in Earth's crust is 27.7 percent and the percent by mass of iron is 5.0 percent, how much more silicon is present in Earth's crust than iron?

Use the circle graph below to answer question 9.

9. The percent by mass of elements in Earth's crust are: 46.6% oxygen; 27.7% silicon; 8.1% aluminum; 5.0% iron; 3.6% calcium; 2.8% sodium; 2.6% potassium; 2.1% magnesium; and 1.5% all others. When oxygen and silicon are not considered, the relative abundance of the remaining elements in Earth's crust are shown in the circle graph above. Which material represents the abundance of calcium?

Short Response

SC.1.14.3

10. How does coal form? Describe the initial material, deposition environment, and geological conditions that lead to its formation.

SC.1.14.4

11. Describe the rock cycle. Discuss what can happen to rock material within the cycle and the amount of time it might take for rocks to be transformed.

12. How does a mineral crystal grow during mineral formation?

SC.1.14.5

13. What are some of the factors that affect the way a crystal grows?

Extended Response

SC.1.14.6

Use photos below to answer question 14.

14. **PART A** Identify each of the igneous rocks shown.

PART B Describe how each rock most likely formed.

Test-Taking Tip

Review Double check your answers before turning in the test.

Short Response

10. Coal usually develops from peat, a deposit of plant matter that has been buried in shallow swamps in temperate or tropical climates. Low levels of oxygen in swamp water slow the decay of the plant matter before it is buried and compacted by sediment. Several stages of compaction drive out impurities, leaving behind a concentrated form of carbon. Coal often lies within repeated sequences of sandstone, shale, and limestone, which indicate alternating continental and marine conditions or low-lying environments near the sea, such as large deltas and swampy coastal plains.

11. Processes of the rock cycle include any chemical and physical conditions that continuously form and change rocks. Some processes happen at Earth's surface, while others happen deep below the surface. Rock material can be changed into igneous, sedimentary, or metamorphic rock. However, many different paths can be taken by rock material as it changes within the cycle. These processes can take extremely long periods of time, occurring over millions of years, or happen suddenly, such as an erupting volcano. As rock material moves through stages of the cycle, all matter is conserved.

12. As the mineral forms, atoms are added to the surfaces, edges, and corners of the mineral crystal.

13. Which atoms are available and their concentration, how fast atoms can migrate, and by the temperature and pressure conditions present

Extended Response

14. **Part A:** The dark, fine-grained rock is basalt. The light-colored, coarse-grained rock is granite.

Part B: Basalt forms from iron-rich magma that cools quickly at Earth's surface. Granite forms from silica-rich magma that cools slowly deep inside Earth.

Rubrics

For more help evaluating Short- and Extended-Response questions, see the rubrics on p. 91.

Section/Objectives	Standards		Lab/Features
Chapter Opener	National	State/Local	Launch Lab: Have you got the time?, p. 645 Foldables, p. 645

Significance of Soil

Chaperon 21

The logical follow-up experiment of 'Significance of Soil' is to find out and measure some soil-borne organisms by following the 'Soil-borne Microbes from the Soil' (SMB from the Soil) protocol for soil-borne fungi and bacteria. The soil-borne organisms also require moist substrate. So, this is a suitable substrate for the growth of soil-borne micro-organisms for cultural and industrial purposes.

Where, watch, think and do the following:

- What is some soil-borne micro-organisms?
- Importance of soil-borne micro-organisms in the soil?

Section Focus Transparency

Alli's Well that Ends Well

Using a transparency, present the story of well water in the south source of Alli's water. As the transparency is read, the students and teacher will discuss the story. As you read, the students will be asked to identify the main problem, the main character, the main conflict, the main solution, and the main outcome. After reading the story, the students will be asked to write a short story about the main problem, the main character, the main conflict, the main solution, and the main outcome.

This is a representation of key blackline masters available in the Teacher Classroom Resources. See Resource Manager boxes within the chapter for additional information.

Key to Teaching Strategies

The following designations will help you decide which activities are appropriate for your students.

- L1** Level 1 activities should be appropriate for students with learning difficulties.
- L2** Level 2 activities should be within the ability range of all students.
- L3** Level 3 activities are designed for above-average students.

ELL ELL activities should be within the ability range of English Language Learners.

COOP LEARN Cooperative Learning activities are designed for small group work.

LS Multiple Learning Styles logos, as described on page 12T, are used throughout to indicate strategies that address different learning styles.

P These strategies represent student products that can be placed into a best-work portfolio.

PBL Problem-Based Learning activities apply real-world situations to learning.

Hands-on Activities

Student Text Lab Worksheet

Graphing Soil Textures

Lab Preview

1. What is a soil?

There are a lot of different types of soil. Some are sandy, some are silty, some are clayey, and some are loamy. Each type of soil has different properties that make it unique. For example, sandy soil is made up of small grains of sand, while clay soil is made up of tiny particles of clay. These different properties affect how the soil behaves, such as how it holds water and how it supports plants.

Real World Problem

Goals:

- Identify the different soil textures.
- Graph the data.

Materials:

Procedure

1. Obtain a sample of soil from a local source.
2. Weigh the soil sample.
3. Add water to the soil sample and mix thoroughly.
4. Allow the mixture to settle for 24 hours.
5. Measure the height of the soil layer.
6. Calculate the percentage of sand, silt, and clay in the soil.
7. Graph the data on a bar graph.
8. Compare the results to the known soil texture classification.

Science Content Background

section

1

Weathering and Soil**Response to Changing Conditions**

Weathering is a natural response to changing conditions in the environment. If a material was created in a specific environment, remains in that environment, and the environment never changes, then weathering should not take place. Exposure to change is an important factor in weathering. The deep-sea environment, for example, is exceedingly constant. Pressure, temperature, salinity, and light levels do not change and weathering is non-existent.

Archeologists find artifacts in the forms of pottery and glass, which have survived thousands of years. These materials are stable on Earth's surface and weather very slowly, if at all. On the other hand, ancient paper or cloth are not as commonly found; they are not stable and are subject to weathering.

Environmental Concerns

A modern environmental concern is that we are creating new synthetic materials that do not weather; i.e. disposable diapers and plastics. In landfills, these materials do not decay, rot, decompose, or weather. These products are also difficult to recycle. Recycling amounts to synthetic weathering and reformation into a new object.

Most fertile soils on Earth have been cultivated for hundreds of years, often with the same crop. This practice results in soil depletion on a colossal scale. A consequence of this is that much of the food grown on or in this soil lacks the nutrient value it once possessed. We are eating food, but it is not as nourishing as it once was. One solution is vitamin supplements for those that can afford them. Unfortunately, many can't afford them. Therefore, soil management and fertility is a concern for everyone.

section

2

Shaping the Landscape**Causes and Effects of Erosion**

The agents of erosion are persistent. These actions are often so gradual that in a person's lifetime, little change to the Earth's surface is noticed. But occasionally catastrophes happen which draw peoples' attention to erosion. It is this harmful set of changes that strips Earth of soil and leads to disasters, such as landslides and flooding.

Running water as an erosional agent is by far the most important. Most of Earth's land surface is affected by this agent. Even in deserts, running water is responsible for most of the surface erosion. Glacial activity is equally destructive, but is confined to mountain peaks and polar regions. Wind erosion is limited to areas with little surface cover and persistent winds.

Human activity, such as road building, farming, and the building of housing, can all promote erosion. Erosion can't be stopped, but it can be controlled and limited. Breakwaters, different farming techniques, and paving less land can all help to reduce it.

section Groundwater

A Precious Resource

The majority of municipal water supplies come from groundwater sources and are built atop those same aquifers. Municipal waste is stored in landfills, which act like giant tea bags, leaching their contents into the groundwater below. Some populations also carelessly dump household waste on the surface and overuse pesticides and fertilizers, which leach into the groundwater supplies.

Conventional wisdom says, “out of sight, out of mind.” It also says that Earth’s soils and rocks will filter out the contaminants and no harm will be done. Earth’s soil and rock cover does filter out contaminants. But like all filters, there is a limit to the rate of filtration and the total amount of contaminants that can be absorbed.

In some regions of our country there are proposals for treating surface water and then injecting it into the groundwater supply, thus bypassing the infiltration process. Many regions use treated surface water. We frequently hear of cities in a water crisis blamed on drought; however, many of these crises are due to natural infiltration being unable to keep up with demand. While infiltration takes years, pumped withdrawal takes minutes.

section Geologic Time

Uniformitarianism

Geologic time is one of the most difficult concepts to understand. Support for the belief in the vastness of geologic time was slow in coming. The principles of relative dating based on the global study of fossils laid the foundation for the concept that Earth was old. If it were not for breakthroughs in chemistry, specifically radioisotope studies, we would still only be using relative dating methods.

Attached to the understanding of relative dating is the concept of uniformitarianism. Set

forth by James Hutton in the late 1700s, this concept unto itself is at the heart of all science. In a nutshell, uniformitarianism says that the laws of nature are fixed and immutable. Chemical reactions occur today as they did yesterday or even a million years ago. The same applies to the laws of physics. And so it goes for all the other laws of nature.

Hutton shocked the geologic community with some simple reasoning. He observed that each year the streams of Scotland flooded and left a new, thin layer of mud on the seafloor. If he dug a hole into that seafloor at low tide, he found a “layer cake” of past mud accumulations. He assumed that each thin layer amounted to a year’s time. Inland there are hillsides exposed by erosion that showed enough of these thin layers to account for hundreds of thousands of years. Hutton properly reasoned that it would take time for the layers to accumulate, be compressed to rock and then uplifted and eroded—the beginnings of the notion of a rock cycle.

Lab It's about time—relative, that is.

Carving A Path

Glaciers have been carving Earth's surface for millions of years. When this glacier eventually melts, it will leave characteristic clues behind that scientists can interpret.

Science Journal In your Science Journal, describe some clues to look for that could indicate a glacier had been there.

644

Theme Connection

Processes The surface of Earth is constantly changing as it adjusts to new conditions. Weathering, erosion, soil formation, and land-form development are the result of a variety of processes as they operate over the immensity of geologic time.

About the Photo

Kennicott Glacier Medial moraines run through the Kennicott Glacier at Wrangell-St. Elias National Park in Alaska. Medial moraines form when lateral moraines converge.

Start-Up Activities

Have you got the time?

We usually think of time in terms of hours, days, and years. Earth processes operate in much longer time units. Imagine that Earth's age—about 4.5 billion years—were equal to an average human lifespan of 75 years. Then one million years of Earth's existence would represent about six days of a human life.

1. Obtain a 5-m length of adding machine tape and a meterstick.
2. Draw a horizontal line across one end of the tape and label it *Present*.
3. Using a scale of 1 mm = 1 million years, draw and label lines across the tape behind *Present* to mark the beginning of each of the following divisions of time:
Cenozoic Era: 66 million years ago (mya)
Mesozoic Era: 248 mya
Paleozoic Era and beginning of Phanerozoic Eon: 540 mya
Proterozoic Eon: 2,500 mya
Archean Eon: 3,800 mya
4. **Think Critically** Eons are the longest subdivisions of geologic time. An eon is subdivided into eras. Infer why eons and eras are different lengths of time. What kind of events might end one time interval and begin a new one?

FOLDABLESTM Study Organizer

Surface Features Make the following Foldable to help you organize features that result from erosion and deposition on Earth's surface.

- STEP 1** Fold one piece of paper lengthwise into thirds.

- STEP 2** Fold the paper widthwise into fourths.

- STEP 3** Unfold, lay the paper lengthwise, and draw lines along the folds.

- STEP 4** Label your table as shown.

Surface-Changing Agent	Erosion	Deposition
Wind		
Water		
Glaciers		

Making a Table As you read the chapter, complete the table describing erosional and depositional features.

Preview this chapter's content and activities at
fl.goescience.com

Purpose to introduce students to the concept and scope of geologic time [L2]

Preparation Pre-cut the adding-machine tape into 5-m-long strips.

Materials adding-machine tape, meterstick, colored pencils

Teaching Strategy Remind students of proper measurement techniques.

Troubleshooting Some students still have difficulty finding millimeter markings on the meterstick. Help students to read the markings correctly.

Think Critically

Students are likely to say that the extinction of a dominant life-form ends intervals. This is true, but point out that most intervals are also accompanied by a global geologic event.

Assessment

Oral Have students speculate about future events that might result in the end of the current epoch (Holocene), period (Neogene), or era (Cenozoic).

New Materials Chemical change results in new substances being formed. Chemical weathering forms new Earth materials. L2

Brainstorm Have students write a new vocabulary word in the center of a sheet of paper. Ask them to brainstorm the meaning of the word and write ideas radiating from the central word like spokes of a bicycle wheel. Students can verify or modify their definitions as they read the text.

Reading Check

Answer action of water, wind, ice, and air

Reading Guide

What You'll Learn

- **Explain** the role of weathering in recycling Earth materials.
- **Discuss** the processes of mechanical and chemical weathering.
- **Describe** the process of and controls on soil formation.
- **Discuss** some methods for controlling soil loss.

Why It's Important

The processes of weathering and soil formation are critical in forming a base to support plant growth and ecosystems.

Review Vocabulary

sediment: particles of rock deposited on Earth's surface that may become sedimentary rocks

New Vocabulary

- weathering
- soil

Weathering

In nature, matter is recycled. Chemical, physical, and biological processes form interconnected cycles that operate to change materials. Because we tend to study each process one at a time, you might get the impression that they stand alone. This is not true. A real understanding of nature comes from learning how the cycles interconnect. Weathering is an example of physical and chemical processes that involve the interaction of air, water, and rock over time.

Natural materials become unstable and break down when exposed to conditions on Earth's surface. **Figure 1** illustrates the

results of rock weathering. The minerals in this rock formed under higher temperatures and pressures compared to those on the surface. When these minerals were subjected to the conditions at the surface, they broke down. **Weathering** is the process of physical or chemical breakdown of a material at or near Earth's surface. Factors that influence weathering include the agent, such as water or air, the nature of the material being weathered, climate, and time. Weathering varies from region to region because different weathering conditions are present.

Figure 1 The corners and edges of rocks are more rapidly weathered than smooth rock faces. This often produces rounded forms.

Reading Check What causes weathering?

Everyday Weathering You can notice weathering going on all around you. Paint on a house eventually will crack or fade in color. Roadways eventually develop cracks and potholes. Some metal items on cars might start to rust. All of these take place at different rates depending on where you live and whether or not you have taken measures to prevent weathering.

Mechanical Weathering

You can think of mechanical weathering as turning big pieces into little pieces. For this to take place, a force must be applied to the material. Forces that can cause mechanical weathering include impact, expansion or contraction of materials, and biological effects. Variables that control mechanical weathering include the nature of the material being weathered, climate, and time. Of these variables, time is the least noticeable. Extremely slow changes often go unnoticed until their long-term accumulated effects get our attention.

Prying Rock Apart If a rock contains natural fractures, water can enter them. When water freezes, it expands. This forces the cracks apart and ultimately forces the rock apart. This type of weathering is called frost wedging. Any place that has sufficient surface water and temperatures that change from freezing to above freezing can experience this type of mechanical weathering.

Growing plant roots are an example of a biological force that can cause mechanical weathering. As roots grow, they increase in diameter and exert forces that widen cracks.

Rocks can also act as impact agents. Large rocks falling from a cliff or tumbling down a slope can break other rocks into smaller pieces. **Figure 2** illustrates what happens when a large object breaks apart. As a large particle breaks into smaller particles, the amount of surface area increases. More surface area compared to volume increases the likelihood that a material will be attacked by chemical agents.

Figure 2 The cube on the right has exposed, inner surfaces that the cube on the left does not have.

SECTION 1 Weathering and Soil 647

Mini LAB

Observing a Disappearing Seasoning

Procedure

1. Sprinkle a teaspoon of sugar on a paper plate. Using the back of a metal spoon, crush the sugar into the finest powder you can. Do the same for a teaspoon of salt.
2. Half-fill four clear drinking glasses with tap water. Allow them to stand for several minutes.
3. Have a watch with a second hand ready. Drop a teaspoon of uncrushed sugar into a glass of water and stir. Record how long it takes the sugar to completely dissolve.
4. Repeat step 3 using the powdered sugar, the powdered salt, and a teaspoon of uncrushed salt.

Analysis

1. Which substance dissolved fastest? Why?
2. How does particle size affect dissolving rate?
3. List some variables other than particle size that could affect dissolving rate.

2 Teach

Mini LAB

Purpose Students will observe the effect of grain size on solution rate.

Materials four clear drinking glasses, salt, sugar, tap water, metal spoons, plastic stirring spoon, clock or watch that shows seconds

Teaching Strategy Have the students attempt to crush the sugar and salt to approximately the same sized particles. Use the back of a spoon against a plate to crush the materials. Running the material through a sieve will ensure uniform grain size.

Analysis

1. powdered salt; because salt is more soluble than sugar
2. smaller-sized particles increase the dissolving rate
3. temperature or quantity of water

Assessment

Oral Have students relate the difficulties they had in doing this procedure. Probable responses might include: determining when the last of the product dissolved—salt is difficult to determine because it clouds the water; making sure the crush size was consistent. Use PASC, p. 89. [L2]

Reading Strategy

Causal Relationships Have students make a chart with the headings *Cause* and *Effect*. Under *Effect*, have students write *prying rock apart*, *moving matter*, *rock rust*, *feldspar weathering*, and *differential weathering*. Have students read the text to determine the cause of each effect.

Illegible Rocks These two obelisks stand 21 m tall. They are made of red granite. Thothmes III erected them in Heliopolis, Egypt around 1500 B.C. In 1200 B.C., Ramses II added inscriptions commemorating his military victories. The obelisks were moved to Alexandria by the Romans in 12 B.C. and sometime later fell over into the mud. It was this unplanned burial that helped prevent chemical weathering of the granite. Unfortunately, the humid climates of New York City and London accelerated the weathering process by reacting with salts contained in the mud.

✓ Reading Check

Answer water, oxygen, and naturally occurring acids

Illegible Rocks The Egyptians carved tall, slender granite obelisks. One is displayed in New York City and another in London. Over time, these two obelisks have become almost smooth and the hieroglyphs barely can be seen. Form a hypothesis stating why the obelisks changed.

Chemical Weathering

The process of chemical weathering forms new compounds and releases elements into the environment. Water and oxygen are the key agents of chemical weathering, along with naturally occurring acids. Elements released by chemical weathering enrich soil and nourish plants. Without weathering of rocks there would be no soil to support land plants, terrestrial ecosystems, and humans.

✓ **Reading Check** List three key agents of chemical weathering.

Matter on the Move Cycles of chemical weathering affect all surface environments from land to sea. If streams carry elements released on land into the ocean, then those elements become raw materials that support marine ecosystems. For example, marine organisms that build shells require dissolved products such as calcium ions (Ca^{2+}) and bicarbonate ions (HCO_3^-) to make their shells. These ions come from the weathering of limestone on land and from the dissolving of other seashells.

Rock Rust Oxidation is a common chemical weathering process. Iron that is present in minerals is released through weathering and combines with oxygen to form iron oxides. You might know that when something made of iron or steel is exposed to air and water, it quickly begins to rust. The mineral hematite is natural “rust” produced through oxidation reactions. Hematite is mined to obtain iron for steel production.

Recall that natural materials tend to convert to a more stable form at Earth’s surface. Unstable iron released by weathering forms stable hematite. Hematite is easily spotted in rocks because it stains them a brownish-red color, as shown in **Figure 3**. Other metals also form oxide minerals. Examples include copper, which oxidizes to a greenish-colored patina or silver, which oxidizes to a black coating.

Figure 3 When iron-bearing rocks are weathered and eroded, they often produce reddish sediment. Iron oxidation also can give some soils a reddish color.

Active Reading

Reflection In this strategy, students record responses to an activity. Have students divide sheets of paper into columns. Have them record their thoughts under headings What I Did, What I Learned, Questions I Have, Surprises I Experienced, and Overall Response. Have students write a Science Journal entry for the MiniLAB in this section.

Elements in Feldspar

Elements in Kaolinite

Figure 4 Chemical weathering changes the chemical composition of minerals and rocks.

Describe how kaolinite is different from feldspar.

Teacher FYI

Feldspar Weathering Carbonic acid causes the mineral feldspar to weather to the clay mineral kaolinite. The chemical reaction can be written as follows:

Caption Answer

Figure 4 It contains hydrogen and no potassium.

IDENTIFYING

Misconceptions

Cave Formation Many students think caves are formed by the work of underground rivers. The process is actually quite different. Students should understand that solid rock once was present where a cave now exists. When rock develops fractures, perhaps from the action of yearly freeze and thaw, water is able to seep into the cracks. Water that is slightly acidic begins to chemically dissolve the rock. As the cracks become larger, more dissolution occurs, eventually forming a cave.

Discussion

Surface Area Water also flows along bedding planes or joints in the rock. Explain to the students that cracks begin to branch out as they increase in size. Ask them to compare these cracks to river drainage patterns. Which one do they resemble? **Cracks resemble dendritic or rectangular patterns.** How does this help in the formation of a cave? As the cracks grow larger, more branches form, increasing the amount of surface area that is exposed to chemical weathering. **L2**

Figure 5 As water seeks a path of least resistance, it acts as a differential weathering agent. This type of weathering creates many interesting landforms.

Feldspar Weathering An important chemical weathering process for continental rocks is the weathering of feldspar minerals into clay minerals.

This reaction starts with a common rock-forming mineral shown in **Figure 4**, and ends with minerals that are common in continental sediment and soil. The silica end product often forms quartz cement in sedimentary rocks. The kaolinite is a clay mineral that helps soil hold water and nutrients. Chemical elements freed by weathering now are available for use by plants. Similar chemical weathering reactions of other minerals provide particles necessary for roots to anchor themselves and nutrient elements to support plant growth.

Differential Weathering Different rock formations tend to weather at different rates. The types of minerals, cementing agent, and the presence of defects, such as fractures, influence how a rock formation weathers. As a result, rocks that are the most resistant to weathering remain in the landscape. They are products of differential weathering and erosion.

Together, erosion and deposition of sediment create a variety of landforms. They also represent important processes of the rock cycle. Landforms, such as those in **Figure 5**, are geologists' clues to the processes taking place on Earth's surface. Some of these processes include floods, landslides, and beach erosion.

Visual Learning

Figure 5 Have students examine the rocks in the photo. Tell them to recall Moh's hardness scale and the three major types of rocks. Why is resistance to weathering based on a combination of factors? **If based on rock type alone, rocks made of soft min-**

erals would be easily weathered. But, limestone bluffs and cliffs such as the Redwall Limestone in Grand Canyon National Park indicate otherwise. Limestone is resistant to weathering in the arid southwest but not in the humid northeast. Here, climate must be considered as well. **L2** **Visual-Spatial**

✓ Reading Check

Answer weathered rock material, organic matter, water, and air

Quick Demo

Soil Components

Materials soil, cookie sheet, colander, plastic jar with lid, tablespoon, powdered dish detergent, water

Estimated Time 15 minutes

Procedure Collect at least four cups of soil and allow it to air dry on a cookie sheet. Sift the sample through a kitchen colander to get rid of stones, twigs, or leaves, and break up any lumps. Place a cupful of the dry soil into a clear, plastic, straight-sided jar. Add a tablespoon of powdered dish detergent and fill with water. Cap and shake for several minutes and set aside. Observe the settling process and record what you see. Sand settles out first, then silt, and lastly clay. It will likely take several days for the final settling. Measure the thickness of each layer and calculate the ratios. This is a rough way to determine the ratio of sand to silt to clay. Ask the students why the dishwashing powder was added to the soil mixture. *The detergent is a surfactant, which helps to separate the particles.*

Caption Answer

Figure 6 Organic materials, fine sediments, and soluble materials are leached from this horizon and transported downward, leaving light materials such as quartz behind.

Soil

One natural resource that is vital to life on Earth is soil. **Soil** is a mixture of weathered rock, organic matter, water, and air that is capable of supporting plant life. Much like human skin, soil is a thin, layered covering of its parent material. Soil originates from weathering of the bedrock beneath it or from materials transported from another location. The raw materials for soil continuously form through the weathering of bedrock below and the addition of organic matter from above.

✓ Reading Check *Soil is made up of what?*

Soil Horizons Digging a deep hole allows you to see the soil horizons, or layers. Each horizon has its own unique texture and color. **Figure 6** illustrates a sequence of soil horizons, called a profile. Soil profiles don't always contain every horizon. The horizons present depend on the composition of the parent bedrock, climate, and the kind and amount of organisms on the surface. In addition, the shape of the land on which the soil forms is important. As slope angles increase, thin, poor-quality soil is more likely to develop.

Figure 6 This illustration provides a generalized view of a soil profile. Soil horizons vary in color and thickness. Some horizons don't appear in certain soils. Notice that the E horizon is lighter in color than the B horizon.

Explain why the E horizon is light in color.

Figure 6 shows a complete set of horizons, designated as O, A, E, B, C, and R from the surface to bedrock. The O horizon, for organic, and the A horizon often are referred to as topsoil. Plants get most of their nutrients from the topsoil.

The E horizon, for eluviation, is a zone in which finer sediments and soluble materials are transported downward. The process of dissolving soluble elements and transporting them deeper into the soil is called leaching. This is much like a coffee maker that leaches flavors from ground coffee. The B horizon collects the materials from above and is usually darker than the E horizon. Sometimes so much material accumulates that water can't easily penetrate this zone. This formation is referred to as hardpan. The E horizon and the B horizon often are referred to as subsoil. Roots from large trees sometimes penetrate these horizons to get water and are able to anchor themselves in the subsoil.

Collectively, horizons O, A, E, and B make up the true soil. The C horizon is partially crumbled and weathered bedrock. The R horizon is unweathered bedrock.

Teacher FYI

Given the same parent material, different climates will produce different soils. Pioneer plants contribute organics to the soil and change its chemistry. Through time, a climax community of plants is

established. Agriculture is largely adaptive in nature. For example, if the native soil supports a climax community of grasses, then agriculture is focused on cultivated grasses—wheat, oats, corn, and barley.

Soil Types There are many different types of soil. Climate often is used as a basis to characterize many different types of soil, as illustrated in **Figure 7**. They are separated according to composition and physical properties. The amount of precipitation and the temperature range of a region, together with the type of parent material, affect the soil that forms. Vegetation, if present, also is important for providing a supply of organic matter. For example, topsoils that develop beneath the forests of the eastern U.S. are acidic, sandy in texture and light in color. This contrasts with soils that develop beneath the grasses of the western U.S. These often are enriched in calcite and are whitish in color. In tropical environments, the soils are strongly leached. They are rich in insoluble aluminum, iron oxides, and clay minerals. Finally, in the arctic or desert regions, where little or no vegetation grows, there is no soil. Without organic material, a true soil cannot develop.

Parent Material Some soils form in the same place as the parent bedrock. Other soils form from materials transported from distant sources. Rivers and glaciers are important transporting agents for soils. Some of the most fertile soils form when rivers flood and deposit new sediment on floodplains or when glaciers transport and deposit sediment. The ancient Egyptians relied for thousands of years on the annual flooding of the Nile River to deposit nutrient-rich sediment. During the most recent ice advance, glaciers in North America transported materials that later would become some of the world's most fertile soils.

Figure 7 Glacial soil in the northeastern U.S. often is composed of poorly-sorted glacial till. The eastern U.S. receives large amounts of precipitation which contribute to wetland soil.

Activity

Soil Texture Using a soils classification triangle, create several soils of your own design. Use a variety of materials from a garden center. Use the triangle to determine the types of soils you have. See how many different soils you can identify. *Students will identify a variety of soils. What is present in each will depend on the type of materials acquired from the garden center. Ordinarily the organic content can be determined by how black the soil is. Judging percentages of sand, silt, and clay is very difficult to do visually. The way the soil feels is often a better technique to use in texture classification.*

Discussion

Soil Type Have the students discuss the role that soil type would have on agriculture in different regions. Why are certain crops grown where they are? *Plants have requirements for growth. Not all soils can support all plants. Is climate the only control? Climate is only part of the control; nature of the parent material also determines soil type. Does climate control the nature of the soil? Yes, heavy rain, for example, can cause erosion or leaching of nutrients; plant growth provides organic material.* **L2 ELL**

Post Reading

Extended Research Ask students to research mechanical and chemical weathering. Have them write a paper that describes a specific example of each weathering type. For example, a student might write about weathering of granitic rock in Yosemite National Park.

DAILY INTERVENTION

Check for Understanding

Visual-Spatial Display unlabeled photos of soil profiles and ask students to identify the soil horizons. Photos can be obtained from your county/state agriculture department. **L2 ELL**

Reteach

Analyze soil samples (as in the Activity) that students have brought in or use homemade soils of your creation. Following each analysis, the students should use the soil classification triangle and determine the amount and kind of changes needed to give the soil a sandy loam texture. If a soil test kit is available, perform tests for nitrogen, potash, and phosphorous. County horticultural agents probably can provide pamphlets for the class on soil amending (fertilizing). **L2**

Assessment

Performance Have students create a community service presentation that focuses on the techniques and values of soil conservation in their region. Use **PASC**, p. 143

Figure 8 The tie-ridging method makes fields look like waffles.

Soil Conservation

Plants and animals continuously remove elements from soil. Soil depletion is a serious agricultural problem in many regions. For example, when the same crop is grown year after year in the same field, particular elements are depleted from the soil. Soils in areas with heavy rainfall, such as rain forests, also tend to be deficient in certain elements. The continuous recycling of plant matter returns these elements to rain forest soils.

Adding Nutrients Soil depletion is most often corrected by the addition of fertilizers containing nitrogen, phosphorous, or potassium. Farmers often use crop rotation to help preserve the quality of soils. This is because what one crop removes from the soil, another crop may return. For example, some crops, such as legumes, return nutrients to the soil. Crop rotation also helps prevent erosion and reduces the risk of diseases and attack by pests. Another alternative is to allow the soil to rest, called going fallow, by not planting crops. This gives the soil time to replenish some of its lost nutrients.

Preventing Soil Loss Most soil lost to erosion occurs because the vegetative cover has been removed or because the land is overly steep. Modern farmers use contour plowing, which runs the furrows around a hill instead of up and down a slope, to reduce erosion. In the tie-ridging method, shown in **Figure 8**, crops are planted on ridges and rainfall collects in basins. Slowing the downhill flow of water helps prevent erosion.

section 1 review

Summary

Mechanical and Chemical Weathering

- Weathering is the breakdown of materials that are not stable under the physical conditions at Earth's surface.
- Physical breakdown of surface materials is accomplished by mechanical weathering.
- Chemical reactions at Earth's surface change mineral composition and release elements.

Soil and Soil Conservation

- Soil is a mixture of organic matter, weathered rock material, water, and air.
- Measures are taken to prevent soil depletion and soil erosion.

Self Check

1. **Explain** how mechanical and chemical weathering processes are related.
2. **Describe** how the controls on soil formation affect soil.
3. **Distinguish** between soil depletion and soil erosion.
4. **Think Critically** Outline the soil conservation measures you expect from any contractor building new roads in your region.

Applying Math

5. **Calculate** Suppose that soil erosion in your area averages 2.65 cm per year. The average soil profile is 3 m thick, and 45 percent of that is topsoil. Estimate how long it will take for the topsoil to erode.

section 1 review

1. Both result from outside forces or processes, which alter Earth materials. An increase in physical weathering leads to an increase in chemical weathering.
2. Possible answers: the amount of moisture will guide the amount of

chemical weathering of rock and plant material; moisture also determines plant growth which in turn contributes to the organic component.

3. Soil depletion is a change in the soils chemistry that effects its fertility; soil

erosion is the physical removal and loss of soil.

4. Where excavation or steepening of slopes will take place, the contractor must take measures to keep soil from eroding—retaining walls, temporary barriers to control runoff; steps should

be taken to limit loss of soil by wind erosion; once construction is finished grass or other plant material must be replaced to anchor the soil.

5. $135 \text{ cm} / 2.65 \text{ cm/year} = 50.9 \text{ years}$

Graphing Soil Textures

Three particle sizes characterize the textures of most soils—clay, silt, and sand. The relative amounts of these three variables plot on a triangular graph. In a triangular graph, a corner represents 100 percent of a variable and its opposite base represents 0 percent of that variable.

Real-World Problem

Different plants require different soil textures. How can you classify soil according to texture?

Goals

- **Graph** data on a triangular diagram.
- **Interpret** graphed data to classify soils.

Materials

soil texture triangular diagram

Procedure

1. Obtain a copy of a soil texture triangular diagram from your teacher.
2. Find the line representing 40 percent clay.

3. Find the line representing 50 percent sand.
4. Plot the intersection of these two lines on your copy of the graph.
5. The remainder of the sample is silt. Your first plotted point represents a soil texture that is 40 percent clay, 50 percent sand, and 10 percent silt, and is called sandy clay.
6. Plot and label the following textures and determine the percentage of silt. Record your answers in a data table.

Soil Texture Data

Sample #	% Clay	% Sand	% Silt
1	20	40	40
2	10	70	20
3	15	15	70
4	60	20	20
5	25	65	10

Conclude and Apply

1. **Describe** the composition of any soil that plots along the base of the triangle.
2. **List** the texture names for each sample.
3. **Evaluate** each sample for its ability to retain or drain water.
4. **Predict** which soil samples would be best for root crops such as potatoes or carrots.

Communicating Your Data

Prepare a brief oral presentation outlining how to use the soil texture triangle.

LAB 653

**BENCH
TESTED**

Real-World Problem

Plants require different soil textures. How can we classify soil textures?

Purpose Demonstrate the use of a triangular diagram to classify soil texture.

Process Skills graph, interpret, infer

Time Required 60 minutes

Procedure

Teaching Strategy Use a transparency of the diagram and a sample problem to illustrate the mechanics of the graph's use.

Troubleshooting Point out to students that if they find the intersection of two of the values, the third value acts as a check. Stress that the base of the diagram is 0 percent and the peak is 100 percent.

Conclude and Apply

1. It contains 0 percent of that component.
2. 1. loam
2. sandy loam
3. silt loam
4. clay/heavy clay
5. sandy clay loam
3. 1. good
2. excellent
3. good
4. very poor
5. good
4. 2 best; 1, 3, 5 good; 4 poor

Communicating Your Data

Have students discuss the variations on opinion that will arise in answering questions 3 and 4.

Shaping the Landscape

Section Focus Transparency

Landscape with Nature
How would you like to never have to mow your lawn again? If that idea appeals to you, landscaping with native plants may be the answer. Native plants flourish since they are well acclimated to the local environment and have little need for pesticides, fertilizers, or any water other than the natural rainfall. Such a natural landscape can make us feel more connected to nature and enhance the beauty of our home environments.

1. How could natural landscaping be good for the soil?
2. How might periodic burning be beneficial for a natural landscape?
3. What is biodiversity?

Causes of Erosion When force is applied to a mass, it may cause motion. The forces of running water, glaciers, breaking waves, gravity, and wind all combine to erode and transport loose Earth materials.

Word Chart Post the new vocabulary words in a prominent place in the classroom. Give students a sheet of paper with definitions and ask them to predict which vocabulary word corresponds to each definition. Students can check their ideas by reading the text and noting the meanings of the words.

Reading Guide

What You'll Learn

- **Explain** how agents of erosion operate.
- **Describe** kinds of landforms created by erosion.
- **Identify** landforms created by deposition of eroded material.

Why It's Important

Some erosion events, such as floods and landslides, have catastrophic effects on lives and property.

Review Vocabulary

physical change: any change in size, shape, or state in which the identity of a substance remains the same

New Vocabulary

- erosion
- sediment transport
- deposition
- drainage basin
- longshore current

Erosion, Transport, and Deposition

You've learned about forces capable of building mountains. Forces with origins within Earth can create uplifted landforms through folding, faulting, or volcanic activity. Although they might seem like permanent features, mountains and other landforms are subject to continuous change. Gravity is a factor in all change. Some of these changes also involve the action of agents at the surface of Earth, such as air, water, or ice. The shape of the land you see is what is left over after material has been removed or added by these agents.

Erosion is the removal of surface material through the processes of weathering. **Sediment transport** is the movement of eroded materials from one place to another by water, wind, and/or glaciers. When a transporting agent drops its load of eroded material, **deposition** occurs. The characteristics of landforms created on the surface, such as the eskers and moraines shown in **Figure 9**, can help identify the type of agent that formed it. Analyzing the sediment in a surface deposit can reveal clues about its point of origin. For this reason surface sediment often is used to piece together the plate tectonic history of a region.

Figure 9 When valley glaciers melt they deposit sediment in characteristic landforms. Moraines consist of poorly sorted glacial till and eskers consist of layers of sediment.

Figure 10 Gradient, or slope, affects the shape of a stream and its containing valley.

Compare and contrast how a steep gradient and a gentle gradient affect the shape of a stream.

Caption Answer

Figure 10 Rivers with steep gradients develop V-shaped valleys and have narrow floodplains. Rivers with gentle gradients develop broad valleys, several oxbows, and have wide floodplains.

Visual Learning

Figure 10 Erosion is occurring at several places in this diagram. Where is deposition occurring? Deposition is occurring in the river channels, on along the river banks, on the river floodplain, and in the delta at the mouth of the river.

Activity

Land Analysis Obtain topographic maps (now available on CD-ROMs) and current local land-use maps for your area. Have students examine these maps to identify remnant landforms and areas of potential erosion and/or flooding.

Running Water

An important agent of erosion that exerts a downward force on slopes is running water. In steep areas, running water cuts down through sediment and rock, creating V-shaped valleys. As the steepness of a slope decreases, more force is exerted sideways. Lateral cutting broadens river valleys and allows for floodplains to develop. The mouth of a river is where it meets the body of water or land surface into which it ultimately flows. Near the mouth, a river might wind back and forth, or meander, across its valley. **Figure 10** shows how characteristics of a river can change as it flows from its source to its mouth.

Drainage Basins In most river systems, small streams called tributaries flow into larger streams, which in turn flow into even larger streams. This process of branching is much like a tree with small branches that can be traced to larger branches, and then to a trunk. Most major river systems are well-known, such as the Mississippi River. All of the land area that gathers water for a major river is the river's **drainage basin**. Drainage basins are larger in area for major rivers and include all of the drainage basins of its tributaries. The Mississippi River drainage basin extends from the Appalachian Mountains westward to the Rocky Mountains. Both of these mountain ranges represent drainage divides. A drainage divide is a boundary line separating distinct drainage basins. **Figure 11** illustrates the Mississippi River drainage basin.

Figure 11 The Mississippi River drainage basin is the largest drainage basin in the United States.

Curriculum Connection

Social Studies As areas were settled, towns sprang up at various locations. Most often these towns were found along the banks of rivers, particularly where obstacles in the river were large enough to require portage around the obstacle. Lakes afforded easy transport, so lake ports were also important. Many of towns have "Falls," "Rapids," "Lake," or the suffix "-ford" in their names.

Have students use a map of your region and highlight those towns or cities which fit the descriptions above. Have them give a reason they think that city was key in the development of the area. Your state museum can probably provide copies of early maps of the state, which show the earliest settlements. Many towns have internet sites which include a brief town history. **L2** **Visual-Spatial**

Mini LAB

 Video Lab available.

Purpose Students will model runoff.

Materials cookie sheet, faucet that will produce a thin, laminar stream of water

Teaching Strategy It is important to stress that the cookie sheet is clean and grease-free and that the stream of water is as fine and laminar as possible.

Troubleshooting Students may need to unscrew the aerator from the faucet to get the fine stream of water.

Analysis

It begins to meander over the sheet more.

The two forces acting in the system are friction and gravity. Assuming that friction is uniform over the surface, we can assume that the water is responding only to gravity. When the sheet is at a steep angle (high gradient) the gravity component is directed straight off the sheet by the shortest path. As the angle of the sheet (river bed) lessens (low gradient) the influence of gravity also decreases. The water flows along the strongest pull of gravity. This translates into meandering.

Assessment

Oral Have the students predict the shape of stream valleys with different gradients. Mountain streams (high gradient) tend to be straighter; streams that are less confined and have a low gradient will develop numerous meanders and broad flood plains. L2

Reading Check

Answer Young streams cut V-shaped valleys. L2

Figure 12 This portion of the Colorado River is cutting a deep, V-shaped valley as the Colorado Plateau is being uplifted.

Mini LAB

Modeling Runoff

Procedure

1. Obtain a clean, flat, smooth **baking sheet**.
2. Turn on a faucet and adjust the flow of **water** to a slow, smooth stream about the diameter of a pencil lead.
3. Place the baking sheet at a steep angle under the stream of water. Hold the sheet so that the water runs off along the length of the sheet. Record your observations.
4. Make several more observations reducing the steepness each time until your last observation is with the stream perpendicular to the sheet. Record all observations.

Analysis

What happened to the stream flow pattern as you decreased the angle of the sheet? Explain.

Channel Development As surface water flows downhill under the influence of gravity, water erodes the surface, creating its own path or following existing paths called channels. V-shaped valleys are formed from rivers cutting down through sediment and rock, eroding material from a slope. Steep canyons can form when downcutting is rapid. This is often a result of a recent uplift of land, as shown in **Figure 12**.

Reading Check

What is the shape of a valley that is cut by a young stream?

Stream Deposits Maybe you've seen accumulations or bars of sediment in stream channels. When running water slows down, it drops part of the sediment load it is carrying, largest particles first. Generally, bars form on the inside of bends in a river channel, where water speeds are slowest. But in regions where sediment is plentiful, bars might interrupt the flow of water right in the middle of the channel, as shown in **Figure 13**.

Figure 13 Streams with many bars within their channels are called braided streams.

Use an Analogy

Oxbow Lakes Meandering streams often develop distinct features called oxbows. An oxbow is a U-shaped frame around an ox's neck used to support a yoke. As water flows along a meander, it slows down on the inside of the bend and deposits the heavier sediment. The water speeds up and flows faster around the outside of the

bend. This causes erosion at this point. Over time, the erosion results in the narrowing of the land between two meanders. This can be seen in several figures in this section. Continued erosion will cause the river to break through the narrow strip of land. This will cause the river to straighten out at that point and will leave behind an isolated lake that is shaped like an oxbow.

Figure 14 The Missouri River, shown above, sometimes overflows its banks and spills onto its floodplain, shown below.

Scienceonline

Topic: Bayou

Visit fl.gpscience.com for Web links to information about the the Louisiana Bayous.

Activity A bayou can be a creek, secondary watercourse, or any of various, usually marshy or sluggish bodies of water. Research the origin of the word *bayou*. Locate the Louisiana Bayous on a United States map.

Floodplains After a river floods, and as floodwaters subside, slow, and drop their sediment, floodplains form along the valley sides. These floodplains are part of a river, but they are only submerged during floods. **Figure 14** shows a satellite image of a portion of the Missouri river before and during the 1993 flood. While they can be catastrophic to property, a beneficial effect of such a flood event is to rejuvenate soil quality.

Deltas At the mouth of a stream that empties into a body of water, a fan-shaped sediment deposit called a delta will form. Deltas often have branching channels, like roots of a tree, called distributaries. Distributaries distribute water and mud into the water body they enter, as shown in **Figure 15**. Similar depositional features, called alluvial fans, form where the mouth of a stream enters dry land.

Figure 15 Both tributaries and distributaries are sometimes compared to branches or roots of a tree. Some distributaries of the Mississippi River are shown here.

Compare and contrast tributaries and distributaries.

Cultural Diversity

Explorers from many different countries led the way into our country. Some places, therefore, have distinct ethnic characteristics. Place names of rivers, towns, and mountains often are Native American in origin. Have your students use state maps to identify features that have non-English names and research the origins of the place names they identify. **L2 ELL** **Visual-Spatial**

Fun Fact

Earth's longest river is the Nile River in Africa, at 6,484 km.
The river with the highest discharge is the Amazon at 180,000 m³/s.
The Amazon also has the largest drainage basin at 5,879,273 sq. Km.

Quick Demo Meandering Streams

Materials sand, baking tray, water

Estimated Time 10 minutes

Procedure A stream table filled with about 3 cm of clean sand-box sand can be used to perform the MiniLAB from this section. You can substitute a large baking tray for the stream table works. Follow the MiniLAB directions. The tray of sand should have a drain that flows into another pan (trap). The trap, in turn, overflows into a sink. The trap is critical so that eroded sand doesn't clog the sink drain. Smooth the sand and change the gradient between trial runs. This apparatus can be left up for student inquiry after the demo.

Teacher FYI

Stream Styles Natural meanders usually start as a stream redirects itself around obstacles in the streambed. These patterns can be quite complex if there are multiple obstacles. At very low gradients or when the streambed is composed of soft mud, streams develop multiple intertwined streamlets. Then it is called a braided stream.

Caption Answer

Figure 15 Tributaries carry water into the main channel, distributaries carry water away from the main channel.

Discussion

Erosion at Home Ask students to identify the kinds of erosion that are taking place in your region today. Extend the discussion to include the forms of erosion that have affected the region in the past and the resulting landforms that exist today. Have them speculate as to how those landforms shaped the land use of the region. **Answers will vary by region—consult your state/local museums and universities for specifics to your region.** For example: thick deposits of glacial outwash and loess in central Illinois formed the basis for the fertile soils and subsequent farming that developed. [L2]

✓ Reading Check

Answer Winter snow fall must exceed summer melt.

Fun Fact

Some well-known features in the United States are actually glacial in origin. Bunker Hill is a drumlin. Walden Pond (Thoreau, 1840s) is a kettle lake.

Caption Answer

Figure 16 A trunk valley is formed when valley glaciers move through regions once occupied by streams. A hanging valley is formed by a tributary glacial valley whose mouth is above the main valley.

ScienceOnline

Topic: Isostatic Rebound

Visit fl.gpscience.com for Web links to information about the effect of the weight of glacial ice on Earth's crust.

Activity In your Science Journal, describe evidence that supports the fact that Earth's crust rebounded upward at a location where the weight of glacial ice was removed.

Glaciers

A region where winter snowfall exceeds summer melt has the potential to form a glacier. This excess snowfall must take place year after year for hundreds to thousands of years. Compaction within a thick mass of snow eventually can change it to glacial ice. Valley glaciers form at the top, or head, of river valleys in mountainous regions. They move down slope, usually following the path of the preexisting valleys as shown in **Figure 16**. Continental glaciers, which occupy huge land areas, cover all but the highest peaks. Ice moves away in all directions from where it accumulates.

✓ Reading Check What is a requirement for a glacier to form?

Imagine what happens when you pour pancake batter onto a cooking surface. It spreads out under its own weight. The more you pour the more it spreads. As ice accumulates, the pressure at its base increases and causes it to flow outward. The polar ice sheets of Greenland and Antarctica move in this manner.

Glaciers become effective agents of erosion as they move either down slope as in valley glaciers or under their own weight as in continental glaciers. As the ice moves, it acts like a giant bulldozer scraping, gouging, and plucking soil and surface rocks.

Figure 16 Valley glaciers create a variety of alpine, or mountainous, features. Along their paths, they accumulate soil and surface rocks that become abrasive material used to transform the landscape.

Compare and contrast trunk valleys and hanging valleys.

Bowl-shaped basins called cirques form by erosion at the start of a valley glacier. Arêtes form where two adjacent valley glaciers meet and erode a long, sharp ridge. Horns are sharpened peaks formed by glacial action at three or more cirques.

U-shaped valleys result when valley glaciers move through regions once occupied by streams. A tributary glacial valley whose mouth is high above the floor of the main, trunk valley is called a hanging valley. The discordance between the different valley floors is due to the greater erosive power of the trunk glacier.

Curriculum Connection

Social Studies Students have learned that Earth's asthenosphere is partially molten and flows under pressure. The extreme thickness and weight of glacial ice causes deformation of the asthenosphere and a decrease in the crust's elevation. When the weight of the ice is removed, the crust rises back up in a process called isostatic rebound. Evidence of this rebound can be observed in areas where large

continental ice sheets once covered the land. Have students discuss the evidence for isostatic rebound provided by Viking ship moorings along the coasts of Canada and Scandinavia. Alternatively, they can discuss the changes observed at Sloop Cove NHS near Churchill, Manitoba. Guide them to note that sea level has not changed appreciably since the time of the Vikings. [L2]

Erosional Features Valley and continental glaciers leave behind deep grooves or striations, which give clues about the direction the ice was moving. Continental glaciers gouged out the Great Lakes and the finger lakes of New York. Valley glaciers convert V-shaped stream valleys into distinctive U-shaped valleys. The downcutting force of valley glaciers differs from those of streams. Rather than simply cutting downward, glacial ice exerts pressure to the sides as well. This creates the distinct and easily recognized U-shaped valley.

Reading Check What is the shape of a valley that is cut by glaciers?

This downward cutting force of ice is a function of mass. Tributary glaciers with less mass cut less deeply. Larger trunk glaciers have more mass and erode more deeply. This produces tributary valleys that enter the main valley at different elevations, creating hanging valleys. Stream divides are eroded into sharp ridges called *arêtes*. Where ice first accumulates, a bowl-shaped depression called a *cirque* is formed. The formation of several cirques around a mountain results in the formation of a horn. **Figure 16** illustrates some glacial landforms that form in mountainous areas.

Glacier Deposits Ice cannot sort material like moving water does. So, when continental and valley glaciers melt, they dump all the rock material they are carrying. This material, known as *till*, is composed of random sediment sizes ranging from tiny clay particles to house-sized boulders. The large ridges of till that accumulate at the edge of a glacier are called *moraines*. An *end moraine* forms at the front of the ice, and *lateral moraines* form at the side of the ice. If two valley glaciers join together down slope, their lateral moraines get sandwiched together to form *medial moraines*. A *ground moraine* forms underneath melting continental ice sheets.

Some of the smaller-sized particles ranging from clay to gravel are carried away by meltwater and form layered deposits on *outwash plains*. Deposits of outwash material are layered and sorted by size because of the action of water in transporting and depositing them. Glacial deposits in flat outwash plains often become fertile soils that support plant growth. **Figure 17** shows examples of landforms deposited by melting ice.

Figure 17 End moraines are composed of poorly sorted soil and rocks that were scraped up by the glacier, moved ahead of it, and then deposited where it melted. Eskers are composed of finer soil and rock material that was deposited within the glacier.

Reading Check

Answer U-shaped

Inquiry Lab

Melting Ice

Purpose to help students visualize till deposition more clearly

Materials two large glass jars with lids, water, assortment of sediment sizes, ice, hammer, large resealable bags

Preparation Fill one jar one-third full with sediment. Add water to fill the jar and put on the lid. Crush the ice inside the plastic bag using the flat side of the hammer. Add sediment to the ice and quickly mix. Pour into the second jar and seal. Immediately put the jar into a freezer.

Teaching Strategies

- Remove the jar from the freezer at the beginning of class. Shake the first jar to free the sediment and set it on the table. Place the second jar next to it. Do not move either jar during the class period.
- Students will observe that the sediment in the first jar will settle out by size, just as it does in a river or stream. The sediment in the second jar will settle out as the ice melts but it will not be sorted. This is what happens as a glacier melts and till is deposited.

For additional inquiry activities, see *Science Inquiry Lab Manual*. L2

ELL

LAB DEMONSTRATION

Purpose demonstrate glacial erosion

Materials sand, large cookie sheet, ice cubes, paper towels

Alternate Materials box lid or shallow box

Preparation Spread a 2- to 3-inch layer of sand on the cookie sheet. Make ice cubes.

Procedure Have a student push an ice cube over the sand and note where the sand erodes and where it accumulates. Have another student push a second cube beside the first. Repeat, but this time have the ice cubes start apart and come closer together.

Expected Outcome Erosion occurs along the bottom and sides of the ice cubes while sand accumulates along the sides.

Assessment

Oral What types of moraines formed? *Lateral, end, and medial moraines formed.*

Caption Answer

Figure 18 Particles are blown by the wind until they are dropped. The leeward side of a dune is protected from the wind. The wind loses energy and the particles are dropped.

Discussion

What are dunes? Obtain photos or transparencies of the five major dune types: transverse, barchan, longitudinal, star, and parabolic. Explain that dune shape is dependent upon sand supply, wind velocity, variation in wind direction, and surface characteristics. Have small groups choose one dune type and speculate on the nature of the four characteristics listed above that result in the formation of their dune. Transverse—large sand supply, constant wind direction perpendicular to dune; points face downwind; Longitudinal—limited sand supply, strong winds from two slightly different directions, parallel to combined wind direction; Star—ample sand supply, three or four wind directions; Parabolic—limited sand supply, constant wind direction, points face upwind. [L2]

ELL  Visual-Spatial

Science Journal

Dust Bowl Experiences Have students write an eye witness account of a “black blizzard” during the dust bowl of the 1930s. Encourage them to discuss why the dust storms were called black blizzards and how these blizzards differ from snow blizzards. Snow melts, and the dust remains where it settles. Information is available from historical societies of any of the dust bowl states, such as Kansas and North Dakota. [L2]

Figure 18 Erosion on the windward side and deposition on the leeward side can cause sand dunes to appear to move.

Infer Why does deposition occur on the leeward side of a dune?

Wind

You might think that wind is the most important agent of erosion in deserts, but this is not so. Running water erodes more, especially during infrequent flash floods. Compared to water and ice, wind lacks the ability to pick up and carry large particles. However, wind can act as a sand blaster, blowing sediment around and polishing and smoothing landforms. In places

where sand and smaller particles are abundant and not held in place by vegetation, wind can be a very effective agent of erosion.

Erosion by Wind The removal of small particles by wind, leaving heavier particles behind, is called deflation. Deserts often are pictured as endless sand dunes, but this is misleading. Many deserts have a rocky, rough texture caused by deflation. The remaining surface is known as desert pavement. Blowouts, or deflation hollows, are common landforms where wind is the dominant agent of erosion. These landforms are shallow depressions where wind has scooped out surface material, leaving high places behind.

Wind Deposits As wind velocity decreases, the load of sediment is dropped. The shapes and sizes of landforms that form depend on how constant the wind velocity is and on the supply of sediment. Fine silt from glacial outwash plains or deserts is picked up and deposited as thick, unlayered deposits called loess (LUS). Dunes form as the wind moves sand-sized particles into distinct forms, as shown in **Figure 18**.

Wave Action

The zone where land meets open water is an area where extreme forces operate. One cubic meter of water has a large mass. The force generated by breaking waves is large and provides the energy to change surface features.

Currents from Wave Action When waves approach a shoreline at an angle, they change directions, or are refracted. They wash up at a slight angle to the beach. The backwash returns to the sea perpendicular to the shoreline. Waves churn up beach sediment, which is carried back toward the sea with the backwash, then moved toward shore at an angle again. This process results in net sediment transport parallel to the shoreline, as illustrated in **Figure 19**. The resulting movement of water parallel to the shoreline is called a **longshore current**.

Differentiated Instruction

English-Language Learners Have students cut photos out of magazines, such as National Geographic or a travel magazine, to create a collage or poster of landforms created by erosion. Students should label or provide a key for their work in both English and their native language. The label should include the erosive agent that created the landform.

Reading Strategy

Panel Discussion Choose five students to be experts for a discussion about erosion. Each expert will study the part of the text that corresponds with one of the following: running water, glaciers, wind, wave action, and mass wasting. Other students in the class will ask questions of the student experts.

Figure 19 Longshore currents run parallel to the shoreline. They can completely remove some beaches by erosion and later deposit the sediment, forming new beaches farther down-current.

Visual Learning

Figure 19 Have students examine the figure and ask the following: The beach is often called a “river of sand.” How can this figure be used to explain this name? The longshore current transports sand parallel to the shoreline. This process never stops, so sand is moving constantly. The movement of the sand can be seen as a river of sand. [L2]

Reading Check

Answer Wave action transports sediment and rolls it around—sediment acts like sandpaper and erodes adjacent particles.

Post Reading

Reflection Ask students to think about a place they’ve seen that has experienced erosion. Have them write a description of the area and an explanation of the erosion process. Write the terms *wave action* and *running water* on the board to prompt thinking.

Erosion from Wave Action The action of waves loaded with sediment works like sandpaper and causes abrasion. This results in rounded pebbles and cobbles on the beach. Coastal cliffs often are eroded at their bases by wave action. This results in periodic collapse of cliff material into the sea. This material then is battered by waves and eventually reduced to smaller sizes that can be transported by the longshore current. Shorelines that are rock-bound with steep cliffs tend to experience differential weathering. A wide variety of landforms, such as sea stacks, sea arches, and headlands, are characteristic of rocky shorelines.

Reading Check How does beach sand become rounded?

Deposition by Wave Action Shorelines commonly lack erosional landforms when they have a thick sediment cover. Instead, the sediment on these beaches is constantly reworked producing a variety of depositional landforms. Longshore currents move sediment along the shore. Where this current slows, sediments are deposited as offshore sand ridges or bars. Sandbars run parallel to the shore. A sandbar that seals off a bay from the open ocean is called a baymouth bar. Spits are sand bars that project into the water from land and curve back toward land in a hook shape. Cape Cod is a well-known spit off the coast of Massachusetts. During severe storms, water levels can rise and create sand deposits known as barrier islands that can serve as protection for the mainland. The shallow lagoons between the islands and the mainland are nurseries for many forms of marine life.

Mass Wasting

When erosion occurs primarily as a result of gravity, whether triggered by an influx of water, by earthquakes, or by human activity, mass wasting occurs. Mass wasting takes place where slopes are overly steep or lacking vegetation. Events usually begin when support at the base of a slope is removed and the material above moves downhill.

DAILY INTERVENTION

Check for Understanding

Visual-Spatial Use the posters created for the Differentiated Instruction or Performance activities as an opportunity for class review and critique. **L2 ELL**

Reteach

Wind Erosion Use eye protection. Use three trays filled with different-sized particles: sand, gravel, or silt. Have students gently blow across the surface of each tray, as if they were blowing out birthday candles. They should repeat this several times, blowing stronger each time. Have them observe the amount of effort it takes to get each particle to begin to move. Silt will take little effort, sand more, but gravel may be immovable. **L1 ELL**

Assessment

Performance Have students create a poster of photos that illustrate landforms created by an erosional agent. Use PASC, p. 145 **P**

Figure 20 In 1985 in Colombia, the Nevado del Ruiz volcano erupted. Meltwater from its glacier-covered peak created a mudflow that took 23,000 lives. In 1991 in the Philippines, Mount Pinatubo erupted and covered its slopes with ash and pyroclastic flows. Heavy rains mixed with the volcanic debris, creating a lahar, or mudflow, that covered much of Bacolor Village, shown above.

Erosion by Mass Wasting Erosion caused by mass wasting is dependent upon the type of event and the type of materials involved. For example, slumps, which are common in soil along hillsides, produce concave, upward scars from which material has detached and moved downward. Landslides or rockslides also can produce distinct scars on slopes. Mudflows move rapidly and are as dense and damaging as fluid cement. These most often occur following heavy rainfall or snowmelt. **Figure 20** illustrates an example of a mass wasting event.

Deposition by Mass Wasting Mass wasting events tend to dump their material in disorganized masses. This material replaces the undermined material at the base of the landform. When sufficient material builds up, the slope becomes stabilized and mass wasting stops. Geologists often can identify ancient landslides by their disorganized structure.

section 2 review

Summary

Erosion, Transport, and Deposition

- Features resulting from erosion, transport, and deposition of sediment give clues about the natural processes that formed them.

Running Water and Glaciers

- Regions along streams have specific characteristics depending on whether they are near the head or near the mouth of the stream.
- Glaciers create characteristic landforms.

Wind, Wave Action, and Mass Wasting

- Wind erosion creates landforms such as blowouts and dunes.
- Wave action creates longshore currents.
- Mass wasting occurs when material moves downslope mainly due to gravity.

Self Check

1. **Define** the general process of erosion.
2. **Describe** the process of sediment transport by running water, glaciers, wind, wave action, and mass wasting.
3. **List** at least two landforms associated with each of processes listed in question 2.
4. **Think Critically** How can you explain a sediment deposit that contains unlayered and randomly sorted material at the bottom and layered, well-sorted material at the top?

Applying Math

5. **Calculate** If a glacier moves 0.5 m per day, how far does it move in 100 years?

section 2 review

1. loosening and removal of weathered material from Earth's surface by an agent of erosion
2. running water: load is transported until velocity decreases—the largest particles settle out first; glaciers: moving ice rafts or pushes sediment along until the ice melts—all the particles

are deposited; wind: wind blown load is limited to sand and smaller particles, which are transported until wind velocity decreases—the largest particles are deposited first; wave action: particles are suspended and deposited with each wave and are transported along the shore by the

longshore current; mass wasting: downhill transport due to gravity, sometimes with the aid of water

3. running water—bars, floodplain, delta, alluvial fan; glaciers—striations, U-shaped valley, moraines; wind—deflation hollows, dunes; wave action—sea stacks, sea arches,

sand bars, barrier islands; mass wasting—slumps, rockslides, landslides, mudflows.

4. The bottom layer was deposited by a glacier; the top layer was deposited by running water.

- water table
- permeability
- aquifer

The Water Cycle

The oceans contain 97.2 percent of Earth's water. That leaves only 2.8 percent as freshwater, three-quarters of which is tied up in glacial ice. This means less than 1.0 percent of Earth's water is available for use.

Water Cycle Freshwater supplies are constantly being replenished through the water cycle. For example, large amounts of freshwater enter the water cycle by evaporation of seawater. A lesser amount enters the cycle through transpiration—the plant process in which water enters roots and is released through leaves as water vapor. The energy to power both evaporation and transpiration comes from the Sun. Water vapor in the air forms clouds, which in turn provide precipitation. Precipitation is freshwater, but it often is contaminated with pollutants washed from the air. Most precipitation goes back into the ocean. The water that falls back on land can evaporate, runoff as stream flow, or infiltrate Earth. **Infiltration** is the process by which water enters Earth to become groundwater below the surface. **Figure 21** illustrates how these processes are interconnected through the water cycle.

Figure 21 The water cycle continually redistributes Earth's water.

L2 ELL

Section Focus Transparency All's Well that Ends Well Chapter 21

For many people around the world, wells are the only source of fresh water. People have been digging wells for thousands of years, yet wells can pose problems. A poorly built well or one that has been tainted by poisonous substances is useless. Fortunately, there are ways to test well water for contaminants, and many people who depend on wells for water perform such tests on a regular basis.

1 How could toxic material spilled on Earth's surface affect groundwater?

2 Why should a person with a well limit the use of pesticides and fertilizers?

L2 Why would water conservation be important for people who get their water from wells?

Reading Preview

Tie to Prior Knowledge

Porosity Fluids can be stored in the empty or pore spaces of materials. Some rocks are able to store water and other fluids. These rocks have porosity.

Predict Meaning Ask students to scan the text to find new vocabulary words. Suggest that they note bold print, headings, and figures for clues to meaning. Have students predict the meaning of each word. Students can then read the text to verify or modify meanings.

Quick Demo

Porosity

Materials glass beakers, non-absorbent materials, water, graduated cylinder

Estimated Time 20 minutes

Procedure Four 500-mL or larger glass beakers can be used to illustrate different porosities. Select three different particle sizes of a non-absorbent material, such as gravel, sand, marbles, ball bearings, or pellets. Fill three of the beakers with a single particle size. Fill the fourth with a mix of the three sizes chosen. Have the students predict the percent porosity for each beaker.

Then pour measured amounts of water into each beaker, recording the amount necessary to cover the particles and fill the beaker.

The amount of water to cover (mL) divided by the amount of particles (mL) times 100 equals porosity. Typical answers should be less than 30 percent.

Teacher FYI

Porosities Single-sized particles (well-sorted) tend to have higher porosities than mixtures of different particle sizes (poorly sorted). Typical rock porosities range from 0–20 percent to as high as 30 percent. Most people tend to overestimate porosity.

Reading Check

Answer the process of surface water seeping into the ground

Groundwater

All the water that is naturally stored underground is called groundwater, as illustrated in **Figure 22**. When water moves underground through infiltration into the pore spaces of sediment and rock, groundwater is replenished. The region near the surface where water can infiltrate freely is the unsaturated zone. The region below that, where water completely fills the pore space, is the saturated zone. The **water table** is the boundary separating these two zones. Factors affecting how easily water can infiltrate and recharge groundwater supplies include the slope of the land, the nature of the surface material, and the type and amount of vegetation.

Reading Check What is infiltration?

Groundwater Storage A material must be capable of absorbing water in order for it to allow infiltration. If a material is not already saturated and enough time is available for water to pass through it, infiltration will occur. Unsaturated, porous sand or gravel will generally allow rapid infiltration. Surfaces made of clay or other impermeable material will generally allow little water to infiltrate. Most rainfall or snow melt runs off steep surfaces or evaporates. Plants take in significant amounts of infiltrated water before the water can move deep enough to be stored. In some regions, the supply of groundwater has been stored for millions of years, but humans are withdrawing it faster than it can naturally be replaced. This is particularly bad in arid climates where rainfall is low.

A rock unit that can transmit water through its pore space is called an **aquifer**. Sandstone and limestone often make good aquifers. A rock that slows or stops infiltration is an aquitard. A shale or clay layer makes a good aquitard. Small, local water tables can happen where an aquitard prevents downward infiltration. In this case water is said to be perched, or positioned above an aquitard.

Figure 22 Groundwater is stored in porous rock called aquifers. It is often recharged, or replenished, by infiltration in wetlands.

664 CHAPTER 21 Earth's Changing Surface

Visual Learning

Figure 22 Note the positions of the saturated and unsaturated zones and the water table. What will happen to the position of the water table after a heavy rain? *It will move up as more ground becomes saturated with water.* L2 ELL

Porosity and Permeability Water infiltrates through pore spaces, which are open spaces in sediments or rock. The combined volume of these spaces defines the material's porosity. If porosity is low or if the pores don't interconnect, then water will not flow easily, if at all. Such a condition is called low permeability. **Permeability**, illustrated in **Figure 23**, is a measure of how well a fluid can pass through a material. Water can continue to move through sediment and rock as long as there are interconnected pores available. This can cause the water table to rise and the zone of saturation to grow. When the water table rises to the surface, water can no longer infiltrate and run-off or flooding from more rainfall is likely.

Figure 23 Fluids pass through interconnected pores but cannot pass through isolated pores.

Applying Math Use Geometry

POROSITY VOLUME Suppose that an aquifer with dimensions of about 450 km in length and 200 km in width is 75 m thick. It has an average porosity of 7 percent. About how much water can the aquifer potentially hold?

IDENTIFY known values and the unknown value

Identify the known values:

Length of aquifer (L) = 450 km or 450,000 m

Width of aquifer (W) = 200 km, or 200,000 m

Thickness of aquifer (T) = 75 m

Porosity = 7% = 0.07

Identify the unknown value: the porosity volume

SOLVE the problem

Volume of aquifer = $L \times W \times T = 450,000 \text{ m} \times 200,000 \text{ m} \times 75 \text{ m}$

$(4.5 \times 10^5 \text{ m}) \times (2.0 \times 10^5 \text{ m}) \times (75 \text{ m}) = 6.8 \times 10^{12} \text{ m}^3$

Total volume of porosity = volume $\times$ porosity (%)

$6.8 \times 10^{12} \text{ m}^3 \times .07 = 4.7 \times 10^{11} \text{ m}^3$

CHECK the answer

Does your answer seem reasonable? Check your answer by dividing it by the porosity, thickness, and width values. The result should be the length of the aquifer in meters.

Practice Problems

The Dakota Sandstone is 925 km long, 560 km wide, averages 4,200 m in thickness, and has an average porosity of 9.3 percent. What is its water storage volume?

For more practice problems, go to page 879 and visit Math Practice at fl.gpescience.com.

Applying Math

Math Standards

National: 1, 4, 9

Florida: MA.B.1.4.1

Teaching Strategy

It is helpful to liken this to determining how much water a sponge can hold when you can't wring out the sponge. Stress that it is a two-part problem: determine total volume of the aquifer and then reduce that value to the amount equal to empty space.

Answer to Practice Problem

$2.02 \times 10^{14} \text{ m}^3$

Activity

Absorption and Infiltration Rate

Have students time the rate at which different materials such as paper towels, cloth, and sponges absorb a given amount of water. Use similar materials to time how long it takes water to soak through (infiltrate) a stack of the same material. **L2**

Reading Strategy

Question a Partner After reading a section, students should write questions to ask a partner. Students will alternate asking and answering questions. The following topics can be used for questions: the water cycle, groundwater, and water resources. Encourage students to write higher-order comprehension questions.

LAB DEMONSTRATION

Purpose demonstrate permeability

Materials juice cans, plastic screens, rubber bands, clock, sand, gravel, tray, paper towels

Preparation Cut one end out of a juice can. Make a large hole (5 cm) in the other end. Construct several more set-ups.

Procedure Place a paper towel over the end of a can with a 5-cm hole, followed by layers of plastic screening. Secure with rubber bands. Fill the can with gravel. Hold the can above the tray and pour water into the can. Time how long it takes for the water to wet the paper. Repeat the procedure with different sizes and mixes of sediment.

Expected Outcome Gravel has the fastest time, then sand, and finally the mixes.

Assessment

Ask students to explain the different flow rates. As pore sizes decrease, friction increases, lowering the permeability. **L2**

Visualizing the Role of Groundwater in Shaping Earth's Surface

Have students examine the pictures and read the captions. Then ask the following questions: Why are karst features most frequently found in areas with limestone bedrock? *Limestone is more soluble in water than most other kinds of rock.* Why can't groundwater be considered a large underground lake? *Because the water is spread out in cracks and openings in the soil and rock.* When groundwater evaporates in a glass, it leaves a solid film, but rainwater does not. What is the film? *Dissolved calcium carbonate from the bedrock.*

Activity

Caves Have students play a block game in which blocks of various sizes and shapes are stacked to form a structure. Carefully remove blocks from the bottom or middle of the stack to form openings and tunnels. Is it possible to create a cave that extends through the structure without causing a collapse? Repeat several times to determine an approximate percentage of blocks that can be removed while keeping the structure intact. **L2**

Figure 24

Some of the rainwater that falls on the ground flows into rivers and lakes. However, much of the water flows between soil particles and travels underground. Below ground, acidic water gradually dissolves limestone. Landforms that result from acidic water dissolving underground limestone are known as karst topography. Indications of karst areas include springs, caves, and sinkholes.

Spring waters flow from the ground where the zone of saturation meets Earth's surface. Depending on the level of the water table, springs can be either permanent or intermittent features of the landscape.

Caves form as acidic groundwater flows through bedrock and dissolves limestone. When the water table drops, open channels remain as caves. Limestone caves can extend many kilometers underground and include chambers that are tens of meters high.

Sinkholes can form when the roof of a cave collapses. Sinkholes can range from small, sloping depressions where water can slowly work its way underground, to large chasms where the flow of a stream or river can be transferred to an underground cave.

Differentiated Instruction

Challenge Have students find the average annual rainfall for your location. If all the rain could be collected, how large an area (in square meters) would be required to supply the water used by a typical household, about 250,000 liters/year? Use the following factors: 1,000 L = 1 m³; one inch = 0.0025 m. **L3**

Water Resources

Life is dependent on the availability of freshwater. Because of this, supplies are monitored and attempts are made to preserve water resources. Humans have a responsibility to protect freshwater no matter what its source is.

Obtaining Groundwater Some groundwater comes naturally from springs, which are where the water table intersects the ground surface. Alternatively, wells are holes dug or drilled into Earth. When a drill hole encounters the water table, water can be pumped to the surface. As water is removed from the zone of saturation, the water table is lowered. You might expect the water table's surface to remain horizontal as water is taken away. This does not happen near the well because the groundwater flow path changes.

Much like surface water, groundwater flows downhill. The natural flow path of groundwater has both horizontal and vertical components, as illustrated in **Figure 24**. Also, groundwater flow rates usually are slow. As water is withdrawn, the direction of water flow shifts downward toward the well, depressing the water table around it into what is called a cone of depression. Depending on the rate of pumping, the cone of depression can affect water availability from other local wells, or force wells to be drilled deeper into an aquifer to obtain water. **Figure 25** illustrates this situation.

Water Under Pressure Wells drilled into aquifers that are under sufficient natural pressure to force water up into a well are called artesian wells. They form when an aquifer is sandwiched between two aquitards. One example might be sandstone positioned between two shale layers. The aquitards keep the water confined to the aquifer. When the aquifer is sloped, gravity on the water provides pressure on the low side of the slope. These wells usually are free flowing at the surface.

Not In My Back Yard (NIMBY) In the past, abandoned mines and parts of uninhabited valleys were used as landfill sites. Trash was thrown into these landfills. When it was discovered that many hazardous materials in trash were leaching into nearby water supplies, something had to be done. Research problems associated with locating sites for landfills and current improvements in landfill technology. Hold a class debate about the pros and cons of landfills.

Science Online

Topic: Hard v. Soft Water

Visit fl.gpscience.com for Web links to information about the difference between hard and soft water and where they occur.

Activity Create a map showing locations of hard and soft water across the United States. Explain what makes water hard or soft and how the effects can be reduced.

Figure 25 As areas become more populated, more water wells often are drilled. This lowers the water table, causing some existing water wells to go dry.
Infer Why is a cone of depression created in the water table at the base of a water well?

Not In My Back Yard (NIMBY) In the past, abandoned mines and parts of uninhabited valleys were used as landfills to hold trash. When it was discovered that many hazardous materials in trash were leaching into nearby water supplies, something had to be done. Research problems associated with locating sites for landfills and current improvements in landfill technology. Hold a class debate about the pros and cons of landfills. **New technology and engineering techniques are continuing to improve the quality of landfill construction.** However, as population increases and availability of land decreases, finding locations for landfills becomes increasingly more difficult.

Discussion

Water Issues Have students compile a class list of actions they could take to conserve water. Introduce local water issues here.

Science Journal

Fluoride—Good or Bad? Provide students with information on the addition of fluoride to municipal drinking water. The U.S. Environmental Protection Agency is a good place to start. Have students write an essay declaring whether this practice is good or not by comparing the pros and cons of fluoride in drinking water. Students should be able to defend their decision. **L2**

Caption Answer

Figure 25 As water is drawn up into the well, groundwater moves slowly through the pore spaces.

Curriculum Connection

Chemistry Introduce the idea of water as the universal solvent and conduct a discussion of how this property creates hard and soft water. To help with this discussion, your local water provider can give you information on the physical properties of the water in your area. If your municipality does not use groundwater, ask your water company to help you locate a nearby town or city that does. **L2**

Differentiated Instruction

English-Language Learners Have students prepare a campaign poster for “Save Our Water” groundwater conservation. Suggest using print-media clippings or drawings and data from your region to keep the campaign local. Another topic could be “Help Control Water Pollution—Do Your Part”. **L2 P**

✓ Reading Check

Answer from natural pollutants, such as arsenic, or infiltration from runoff

Caption Answer

Figure 26 Polluted groundwater is sometimes impossible to clean.

Post Reading

Illustrations Have students create illustrations of groundwater moving through rock. Ask them to label impermeable rock, saturated and unsaturated zones, and the water table. Also, have them draw and label a sketch of the water cycle.

3 Assess

DAILY INTERVENTION

Check for Understanding

Auditory-Musical Have students write a jingle or song with lyrics describing the water cycle. [L2]

Reteach

Obtain information from your local or state water conservation organization that addresses local water concerns. Have the students read through the information and list the problems their area is dealing with and any solutions that have been employed. [L2]

✓ Assessment

Content Have students outline factors in their region that have an effect on the amount and quality of the region's groundwater. Ask what can be done or is being done in their region to protect their water supply. For regions that use surface water as the source, apply the same ideas and ask why groundwater is not used. [L2]

Figure 26 Pollution can enter groundwater through infiltration. Cleaning polluted groundwater can be difficult and costly.

Infer Why is it important to prevent groundwater resources from being polluted?

Pollution and Groundwater Resources Pollutants that are spilled or dumped on the ground and even air pollutants, washed from the air by precipitation, enter groundwater through infiltration, as shown in **Figure 26**. Particles of soil can filter larger contaminants and prevent them from moving deeper. But, natural pollutants such as arsenic can contaminate infiltrated water. Such groundwater is not useful as a freshwater source.

✓ **Reading Check** How can groundwater become polluted?

section 3 review

Summary

Water Cycle

- Only about three percent of Earth's water sources are freshwater. Freshwater is renewed through water cycle processes.
- Supplies of groundwater are replenished when surface water infiltrates into Earth.

Groundwater

- The slope of the land, nature of the surface material, and the kind and amount of vegetation control infiltration.
- Porosity, permeability, and gravity control how water will move through materials.

Water Resources

- Both surface and groundwater resources are susceptible to human and natural contamination.

Self Check

- Explain** the importance of groundwater.
- Discuss** the role of porosity and permeability in the transmission of water through rock.
- Distinguish** among the unsaturated zone, the saturated zone, and the water table.
- Think Critically** In a rapidly growing neighborhood, streets, shopping centers, and homes are being built. Discuss the possible long-term effects of such growth on groundwater infiltration and supplies.

Applying Math

- Calculate** Suppose a community of 1,500 uses water at a rate of 1,000 L per person per day. This community relies on an aquifer that contains 1.5 billion L of water. How many years will this water supply last?

section 3 review

- Groundwater is the source from which most communities draw their water supply.
- Porosity determines the quantity of water that can be stored; permeability determines the ease of transmission of water between the pores.
- The unsaturated zone has pores that are not filled with water, the saturated zone has pores that are filled with water, and the water table is the boundary separating the two.
- These factors limit infiltration and increase runoff and flood potential; if unchecked, less water will enter the ground and groundwater supplies can be used up.
- 1,000 days or 2.7 years

Geologic Time

Reading Guide

What You'll Learn

- **Distinguish** among geologic eras, periods, and epochs.
- **Explain** how scientists decide when a geologic time period ends and another begins.
- **Explain** the methods and logic used in relative dating.
- **Interpret** a geologic cross section.
- **Describe** the methods and logic used in absolute dating.

Why It's Important

An understanding of geologic time allows you to put current geologic events into a realistic perspective.

Review Vocabulary

radioactivity: the process that occurs when a nucleus decays and emits alpha, beta, and gamma radiation

New Vocabulary

- absolute dating
- relative dating
- uniformitarianism
- principle of superposition
- unconformity
- fossil

Time

In your daily life you have become accustomed to the length of a year, a day, or an hour. These units of time are ancient and were established by observing astronomical events. **Figure 27** shows a globe illustrating Earth's time zones. They are determined by the position of Earth with respect to the Sun during one cycle of Earth's rotation.

Absolute and Relative Dating You can give your age in years, months, days, and even hours. To do this you must have a starting reference—your birth date. Birth records often give the exact hour and minute of birth. This is an example of absolute dating. **Absolute dating** is the process of assigning a precise numerical age to an organism, object, or event. Technology allows scientists to add precision to their findings involving geologic time.

Relative dating is the process of placing objects or events in their proper sequence in time. When you date events relatively, you know which came first, second, and so on. For example, students could be asked to line up in order of birth date, with oldest first. The key to relative dating is that the order is controlled by logical relationships, which might or might not involve the use of numbers.

Figure 27 Earth is divided into 24 time zones.

1 Motivate

An editable Microsoft® PowerPoint® presentation is available on **Interactive Chalkboard** CD-ROM.

Discussion

Time Have students define *time* in their own words and then describe the methods used to establish common units of time—day, month, and year. **day** = repetition of the Sun on your meridian; **month** = repetition of a full moon on your meridian; **year** = repetition of the Sun at its highest or lowest point in the sky. [L2]

It's how old? James Hutton is considered the father of modern geology. Research Hutton's life to discover how he became such an important scientific figure. **James Hutton profoundly changed people's thinking.** He was controversial in his day, just as Charles Darwin was some years later for his view on the origin of species. Hutton's observations led to the modern notions of a very old Earth.

Reading Check

Answer statement that says that oldest rock layers occur at the bottom of a formation, and become younger upward

Quick Demo

Fossil or Just Bone

Materials bones, fossil bones

Estimated Time 10 minutes

Procedure Obtain some clean bones from a butcher. Contact a college or state museum to borrow some fossil bones. Have the students handle both and briefly discuss how they are different. Ask the question: How does a forensics expert know if the bones found in a woods are recent or fossils? **Fossils will have been replaced by mineral matter and should be heavier and denser than recent bones.** Replacement can change the color of the bone as well; brown or black usually indicates replacement by the mineral phosphate. Variegated colors often indicate silica replacement. [L2]

It's how old? James Hutton was instrumental in changing the way scientists think about Earth history. Research Hutton's life to discover how a gentleman farmer became such an important scientific figure.

Figure 28 The principle of cross cutting relationships often can be used to determine the chronological order of some of Earth's geologic events. This illustration shows an intrusion of igneous rock that was separated later by a fault.

Uniformitarianism Geologic time is so vast that when James Hutton introduced his ideas for relative dating of rocks in his native Scotland and proposed that they might be millions of years old, he was seriously doubted. Hutton proposed the idea of **uniformitarianism**, which states that the laws of nature operate today as they have in the past. The only changes might be in their rate or scale. By studying how geologic events take place today, scientists can infer how events took place in the past. Uniformitarianism often is stated "the present is the key to the past." The idea of uniformitarianism is supported by many observations.

Principles of Relative Dating

To accurately date an event requires a set of logical rules that help determine the order of events. In the mid-1600s, Nicolaus Steno, a Danish physician, stated four principles that became the basis for understanding geologic events and the order in which they occurred. Suppose you were throwing papers into a wastebasket all day long, and at the end of the day you discovered you needed to find a paper from early that morning. You would know to look at the bottom of the basket, because the first things tossed away, or oldest papers, are at the bottom. In much the same way, the **principle of superposition** states that the oldest rocks in an undisturbed sequence of rock layers will be at the bottom of the sequence.

Reading Check What is the principle of superposition?

Original Horizontality In formulating the principle of original horizontality, Steno recognized that sedimentary layers always start off as horizontal layers. If you saw sedimentary layers that were not horizontal, you should know that they had been disturbed. You could infer that they began as horizontal layers of sediment, were formed into rock, and then were moved out of the horizontal position by some force.

Overlapping Features Another point of logic that helps establish a relative age is the principle of cross cutting relationships. This principle states that any rock formation or fault is younger than the rock or feature that it cuts through. How could an igneous rock intrusion squeeze through something that is not there? It seems apparent that the rocks affected by the intrusion in **Figure 28** had to be there first in order to be affected. Likewise, if a piece of rock were to become embedded in part of another rock, the piece had to exist before the rock into which it was incorporated. These rock pieces are called inclusions.

Science Journal

Travel Log Have students pretend that they are time travelers on a journey through one of the geologic eras. Have the students write a science log for their journey from the beginning to the end of the era. The log should include descriptions of the animals and plants they saw along the way. A complete journal would include some geologic events as well.

Reading Strategy

Determine Main Ideas Have students determine main ideas for the following sections: Time, Principles of Relative Dating, Fossils, Absolute Dating, and Geologic Maps. Remind them that main ideas can be implied. Encourage students to put themselves in the author's place and examine phrases for clues to what is important.

Unconformities Rock sequences are like Earth's diary. If you keep a diary there might be days when you make no new entries. Also, there might be days when you make entries, but tear them out later and destroy them. Deposition is similar. Rocks that occur in their proper time sequence might have gaps within the sequence. There are times when no sediments are being deposited that can be observed later. Also, there are times when erosion destroys existing rock layers. **Unconformities** represent gaps in the rock record during which erosion occurred or deposition was absent. **Figure 29** shows a sequence of rocks that contains several unconformities.

Reading Check What is an unconformity?

Fossils

The remains or traces of organisms found in the geologic rock record are called **fossils**. Fossils can be direct remains, such as an actual bone or shell. Sometimes fossil remains, such as the inside of a shell, act as molds that form casts when filled with sediment that later hardens to rock. In a process called replacement, water containing dissolved mineral material might replace original shell or bone material with different minerals such as pyrite or quartz. In other cases, only a trace impression such as a footprint or burrow is left for paleontologists to observe.

Correlation While working as a canal engineer in England at the end of the eighteenth century, William Smith proposed the principle of faunal succession. Smith noticed that fossils appeared in the same order in the rock layers dug out to build the canals, no matter where he found them. For example, if fossil Q were found in a sedimentary rock layer above fossil F, then Q also appeared above F in a different geographic region. If you apply the law of superposition to this observation, you can conclude that fossil Q is younger than fossil F.

The process of matching distinctive rock units from different regions is called correlation. **Figure 30** illustrates how this is done. Paleontologists have been successful in correlating fossil-bearing rock units on a global scale. Fossils that are most useful as global time markers often are from organisms that were widespread geographically, but lived in only a narrow, well-defined period of time. Such fossils are called index fossils.

Not all fossil organisms existed over a wide area, however. Some fossils are not useful as time markers because they appear the same over millions of years. In addition, recall that geologic processes such as mountain building and erosion can destroy fossils, making correlation difficult.

Figure 29 Three types of unconformities are shown above: disconformity, angular unconformity, and nonconformity. A disconformity is an erosional surface between horizontal rock layers. An angular unconformity is an erosional surface between rock layer segments that intercept at an angle. A nonconformity is an erosional surface between sedimentary rock and igneous or metamorphic rock.

Figure 30 Sometimes the relative age of rock units can be found by matching distinctive fossil-bearing rock units from different locations.

SECTION 4 Geologic Time 671

Reading Check

Answer a gap in the rock record caused by periods of erosion or non-deposition

Quick Demo Molds and Casts

Materials paper cups, plaster of paris, water, petroleum jelly, cotton swabs.

Estimated Time 15 minutes per day (2)

Procedure Mix the plaster of paris to the consistency of peanut butter. Half-fill a paper cup with plaster of paris. Coat an object with a very thin film of petroleum jelly and press it into the plaster surface to make an impression. Do not push it in all the way. Set it aside to harden. The next day, remove the object and coat the entire top surface of the plaster in the cup with a very thin film of petroleum jelly. Cotton swabs help with this. Fill the cup with a second batch of plaster. Set it aside to harden. The next day, peel the paper cup away and separate the two halves. If done properly, a large amount of detail will be preserved. The bottom half is a mold; the top half is a cast.

Teacher FYI

Fossils Very few fossils are actual remains. The most common forms of fossils are molds and casts and replacement fossils. In replacement fossils, minerals in groundwater replace the original bone, shell, or wood of the organism. Details and internal structures are well preserved. For example, thin slices of petrified wood show cell walls of the original wood. The fossils are denser and heavier than the original material.

Visual Learning

Figure 29 An unconformity is a surface that represents a break in the geologic record. Usually a disconformity can be detected only by studying fossils in a sequence of sedimentary rock layers. A disconformity can occur when a surface is eroded and sediment is deposited on it at a later time. A disconformity also can occur when significant geologic time passes between depositions. **L2 ELL**

Differentiated Instruction

Learning Disabled Have students mix the plaster for the mold and cast activity. The plaster mix should not be too watery. A watery, soupy mix dries too slowly and the objects sink into the plaster. **L1**

Teacher FYI

As time passes, there is an increased possibility that evidence needed for dating will be destroyed. With this scant evidence, precision is lessened; therefore, the limits of each time segment are set by very noticeable or revolutionary changes in the rock and fossil record.

In more recent rocks there is an abundance of evidence and therefore finer definitions of time are possible.

Use Science Words

Prefixes Have students research the meaning of some of the prefixes used in the geologic time scale.

Paleo = *old/ancient*

Meso = *middle*

Ceno = *new*

Oligo = *little/few*

Neo = *new*

Eo = *dawn*

Mio = *less*

Holo = *entirely*

IDENTIFYING

Misconceptions

Time Relationships Films often portray dinosaurs and humans in the same scenes. The last dinosaur died millions of years before the first humans appeared. It is worthwhile to consult a geologic time scale and review the first occurrence of major animal and plant groups.

672 CHAPTER 21 Earth's Changing Surface

Geologic Time Scale Historians speak of the Industrial Revolution, and musicians refer to the Classical Period. These time periods began and ended with some event that marked a noticeable change in society and music. Similarly, paleontologists observe changes in the fossil record and associate them with boundaries of time units, shown in **Figure 31**. At these boundaries, fossils of certain life forms are no longer present and new life forms begin to appear. Boundaries also might be established by evidence of a catastrophic geologic event. Such events might have caused environmental changes that led to extinctions or changes in life forms.

Absolute Dating

Some atoms in minerals of a newly-formed igneous rock are like a clock that has been reset. A quantity of unstable radioactive element—the parent isotope—starts its decay at the time of mineral formation and gradually decays to a stable daughter isotope. Because radioactive isotopes decay in predictable ways, scientists can analyze the ratio of parent to daughter isotopes in a mineral to calculate the time that has elapsed since that mineral formed.

Radioactive Decay Some types of atoms are unstable and decay by casting off, or emitting, parts of their nuclei. Decay mechanisms produce new isotopes—some produce daughters with different atomic numbers, some involve a change in atomic mass, and some involve a change in both.

Figure 31 Phanerozoic means “visible life.”
Calculate What fraction of Earth’s history does the Phanerozoic eon represent?

Visual Learning

Figure 31 Have students examine the geologic time scale and note how each era is subdivided. Ask students to suggest reasons why the Cenozoic is subdivided into more units than the other eras. The Cenozoic contains the youngest rocks on Earth and the youngest fossils. There has been less time to destroy fossil material. Because the abundance of fossils is higher in these younger rocks, the formations can be subdivided with greater detail. L2

Fun Fact

Most dinosaur skeletons found in nature aren’t complete. The bones become scattered and many are not preserved. Skeletons displayed in museums display those available bones. The curators create copies of the missing parts. For example, if the right foreleg is found, but there is no left foreleg, the right is used as a model for the missing left.

Table 1 Commonly Used Isotopes for Dating Earth Materials

Radioactive Parent	Stable Daughter	Half-Life
Carbon-14	Nitrogen-14	5,730 years
Uranium-235	Lead-207	713 million years
Potassium-40	Argon-40	1.3 billion years
Uranium-238	Lead-206	4.5 billion years
Thorium-232	Lead-208	14.1 billion years
Rubidium-87	Strontium-87	49.0 billion years

Half-Life Every radioactive isotope has a half-life. The half-life is the time it takes for one-half of a radioactive parent sample to decay to its stable daughter. After one half-life, the ratio of parent atoms to daughter atoms is 50:50, or 1:1. For example, if the half-life of a parent isotope is 500,000 years and a rock is analyzed and the observed daughter/parent ratio is 1:1, one half-life has elapsed and the age of that rock is 500,000 years. During the next half-life, there is decay of one-half of the remaining parent isotope, resulting in one-fourth parent to three-fourths daughter, or 25:75.

Reading Check What is half-life?

Useful Isotopes All of the isotopes in **Table 1** except carbon-14 are common in many types of rocks. Carbon-14 is useful for dating organic Earth materials such as wood and peat.

Generally, absolute ages are determined from unaltered minerals in igneous rocks. This is because sedimentary and metamorphic processes involve water or other fluids. When they interact with the rock it can cause the amount of parent isotopes, daughter isotopes, or both to change. When this happens, the age that is determined will be too young or old.

To see how geologists combine relative dating techniques with absolute dating techniques, look at **Figure 32**. You could conclude from the rock layers at Location A that Fossil C is between 2.1 and 2.4 million years old, Fossil A is older than 2.4 million years, and Fossil E is younger than 2.1 million years. These conclusions use radiometric dating for the age values and superposition for the order of events. What age relations can you determine for Fossils C, B, E and F at Location B?

Figure 32 Relative dating and absolute dating techniques can be combined to help determine the ages of some fossils.

Infer Why is Fossil C considered to be between 2.1 and 2.4 million years old?

SECTION 4 Geologic Time 673

Content Background

Radioactive decay occurs when unstable atoms spontaneously break apart releasing alpha particles making them a more stable element. The rate at which the atoms decay depends on the element. Radiocarbon dating was recently used to determine the fate of a set of human skeletal remains found near Kennewick, Washington. If they could be determined to be Native American, they would be protected by the Native American Graves Protection and Repatriation Act of 1990 (NAGPRA). In 1999, four small bone samples were tested at three independent laboratories. Results indicated that the chronological age of the bones is between 9510 to 9320 years ago. This age predates the arrival of any European explorers. So, the remains are considered to be Native American.

Reading Check

Answer applies to radioactive isotopes; is the length of time required for half the set amount of an isotope to decay to its stable daughter product

Caption Answer

Figure 32 The rock layer below Fossil C has been radiometrically dated to be 2.4 million years old, the rock layer above Fossil C has been radiometrically dated to be 2.1 million years old.

Reading Check

Answer a two-dimensional representation of the rocks at Earth's surface

Make A Model

Geologic Structures Students enjoy making models of geologic cross-sections or geologic structures. Anticlines, synclines, basins, domes, or more elaborate cross-sections can be made of any material. A novel twist is to create them from edible materials.

A variation is to create a cross-section cake, where the icing hides the structure. Straws pushed through the cake act like drill cores. Students can infer the structure and test their hypothesis by cutting (and eating) the cake.

L2 ELL N Visual-Spatial

Caption Answer

Figure 33 uplift from below the rock layers, or lateral forces converging toward a central area

Figure 33 Tectonic processes can cause Earth's plates to shift, collide, and separate. Sometimes this leads to the deformation of horizontal rock layers.

Infer What direction(s) of force might be needed to create a dome?

Geologic Maps

Geologic cross-sections, like the simplified sketch in **Figure 32**, represent a vertical slice taken through Earth. Geologic maps, on the other hand, show the horizontal surface distribution of various rock formations. Most geologic maps also include a legend that indicates the ages of the rock formations at the surface. Geologic maps are two-dimensional models of Earth's crust for a given region. Geologists plot the location, orientation, and boundaries of rocks found at the surface. These data are obtained by direct field observation, through drill cores, aerial photography, and satellite observations.

Reading Check What is a geologic map?

Basins and Domes Recall that rock layers can be deformed by tectonic processes that result in the formation of faults and folds. One example of a deformed structure is a basin. Recall that the principle of original horizontality states that sediments are laid down in horizontal layers as shown in **Figure 33A**. Compressional forces due to plate tectonic activity cause the layers to fold and to dip downward. **Figure 33B** shows the surface map expression of a basin. In basins, the youngest rocks are exposed in the center and tilt or dip inward.

Domes are essentially the opposite of basins. In this case, the rock layers are uplifted at the center of the structure. The surface appearance of a dome, shown in map view in **Figure 33C**, is similar to a basin. In this case, the oldest rocks are at the center and dip outward. Visualize this by warping up a stack of papers into a hill. Next, imagine sawing off the top of the paper hill. The sawing would expose the bottom layers of paper in the middle. In the case of rock formations, the sawing represents erosion, and the lower paper layers represent the oldest rock layers.

Folds Folding of the crust can also be recognized on geologic maps. Recall that compressional stresses tend to squeeze and shorten materials. If the forces on part of Earth's crust are mainly compression forces, then rocks subjected to the compression might wrinkle up or fold. Hold a sheet of paper flat with both hands and push the sides together. The paper wrinkles either up or down. Folds of rock appear much the same way. An upward wrinkle of rock formations is an anticline and a downward wrinkle is a syncline, shown in **Figure 34A**. Try the paper trick again, but hold one hand still and push with the other. You get a fold that flops over horizontally. This is called a recumbent fold.

Visual Learning

Figure 33 Examination of the diagram indicates that up-folded layers should form a mountain and down-folded layers should form a valley. However, a well-known rock exposure in the Appalachian Mountains of Maryland exhibits the opposite. The road cut through the mountain

shows down-folded layers. Ask students how this might be possible. **Accept reasonable answers.** The Appalachian Mountains are so old that erosion has worn down the original high mountains. In many places, what once were valleys are now the high points, thus down-folded layers make up what are now the mountains that we see. **L2 ELL**

Figure 34 Two basic types of folds are found in rock layers.

A Synclines form a trough and anticlines form an arch.

B If these folds are tilted, they form plunging folds. On a geologic map, plunging folds appear as V-shaped or horseshoe patterns.

Plunging Folds The axis of a fold is an imaginary line where Earth's surface meets the axial plane. The axial plane divides the fold in half, and is usually perpendicular to the compression force. If the forces are applied unevenly the axis of the fold might plunge back into the Earth, producing a surface pattern of rock like the one shown in **Figure 34B**.

These structural features can give you an idea of how geologists illustrate what the surface of the crust looks like in given locations. Practice viewing the structures in cross section and map view, and apply relative dating logic to the structures. You will soon be able to reconstruct the events that formed the features, and tell a story about their history.

section 4 review

Summary

Time

- Uniformitarianism states the processes occurring today are the same as they have been in the past. Rate and extent may have changed.

Principles of Relative Dating

- Steno's principles helped to develop an understanding of geologic events.

Fossils

- Fossils are the remains or traces of once-living organisms. Correlation is the matching of rock outcrops from one region to another.

Absolute Dating

- Analyzing the radioactive decay of radioactive isotopes helps to establish numerical dates for objects and events.

Geologic Maps

- Geologic maps are two-dimensional models of a region of Earth's crust.

Self Check

- Discuss** how events in Earth history determine boundaries for geologic time units.
- Compare and contrast** absolute and relative dating.
- Describe** three lines of logic used in relative dating. Draw and label respective diagrams.
- Think Critically** You're hiking down a canyon that has been deeply eroded, exposing numerous folds. One fold is recumbent, with layers turned completely over. Describe the problems this structure could cause for relative dating, if only a small portion of its rock layers were exposed.

Applying Skills

- Calculate an Age** Suppose the ratio of radioactive parent to stable daughter isotope in a mineral within an igneous rock is 12.5:87.5. The half-life of the parent isotope is 7.13×10^8 years. How old is the rock sample?

More Section Review fl.gpscience.com

SECTION 4 Geologic Time 675

section 4 review

- Mass extinction of key animal forms or global geologic events establish boundaries.
- Both are used to establish time relationships; absolute dating establishes numerical dates while relative dating establishes the order of events.
- superposition—oldest material is at the bottom of an undisturbed sequence of rock; cross-cutting—features which cut across other features are younger than the feature they transect; original horizontality—sedimentary rocks start off as horizontal layers
- The dates would be in reverse order, but fossil inclusions may alert you to the reversed order.
- $3 \text{ half-lives} \times 713,000,000 \text{ years} = 2.1 \text{ billion years}$

MA.B.1.4.2

Post Reading

Fix-Up Strategy Model this strategy by reading a challenging passage aloud. As you read, ask clarifying questions, change reading pace, review figures, and reread when necessary. Have students practice the strategy with a partner, using a passage they find particularly difficult.

3 Assess

DAILY INTERVENTION

Check for Understanding

Visual-Spatial Have the class construct a living geologic time scale on the school's football field. Assuming Earth is 4.5 billion years old, 1 inch equals 1,250,000 years. Have students make large pennants on stakes to mark geologic and biologic events on the time line. **L2 ELL**

Reteach

Use the Launch Lab time line that was created and have the students add detail to it by including periods, eras, and epochs. Have them illustrate the timeline by correctly sketching in the animals and plants common to specific periods. **L1 ELL**

Assessment

Create Have each student prepare a game-show-style answer that asks a question for the category *Geologic Time*. Critique each answer and use the best answers for an end-of-chapter review. Use PASC, p. 91. **L2**

Real-World Problem

Purpose Demonstrate the methods used in relative dating of geologic cross sections.

Process Skills observe, interpret, infer

Time Required 90 minutes

Procedure

Teaching Strategy Have students carefully examine the example(s) given and stress that the list of events will include more than just the layers of rock shown in the cross section.

Analyze Your Data

Expected Outcome Students will be able to apply the laws of relative dating.

Answers to Chronologies

Tiltin Hilton

1. B conglomerate
2. C sandstone
3. D limestone
4. F sandstone
5. G shale w/inclusions of F
6. tectonic movement
7. angular unconformity
8. L conglomerate
9. M limestone
10. N shale

Criss Cross

1. F sandstone
2. angular unconformity
3. M limestone
4. O shale
5. S limestone
6. T conglomerate w/inclusions of F
7. disconformity
8. W shale
9. G intrusive igneous rock any time after S

10. H intrusive igneous rock anytime after G and S

No Fault of Mine

1. A limestone
2. C shale
3. D sandstone
4. F limestone
5. G conglomerate
6. disconformity

7. I shale
8. J sandstone
9. Fault X

Intruder

1. Q limestone
2. R sandstone
3. S extrusive igneous rock
4. K sandstone
5. T extrusive igneous rock

6. C shale
7. folding
8. angular unconformity
9. B sandstone
10. disconformity
11. M shale
12. N intrusive igneous rock anytime after B sandstone

It's about time—relative, that is.

Real-World Problem

When interpreting the geologic history of a region, geologists follow the principles of relative dating. As with all scientific disciplines, they might get help by exchanging information with other scientists. Some rocks in an area of interest might have been dated using radioactive isotopes or index fossils. How can geologists determine a chronological order of events that took place in a section of Earth's crust over many millions of years?

Procedure

1. Familiarize yourself with the symbols in the legend that signify different rock types and other cross section features.
2. Examine the cross sections. On your own paper, list the order of events that took place for each cross section, listing the oldest first. Note that the number of steps is not simply the number of rock layers in the cross section.

- Goals**
- **Observe** geologic cross sections.
 - **Interpret** events that caused the observed features.
 - **Infer** a probable chronology for the events.

Materials
copies of geologic cross sections

Using Scientific Methods

- Be sure to include all of the events or actions that changed or helped form the Earth materials shown in each of the four cross sections. For example, unconformities, faulting, folding, or other changes also need to be placed in proper order.

Analyze Your Data

- Analyze** each cross section and determine whether there is more than one possible chronological interpretation.
- Identify** features that are most useful in supporting relative age relationships.

Conclude and Apply

- Evaluate** cross sections that apparently have more than one possible explanation for a geologic history.
- Explain** whether or not the absolute ages for the intrusions in cross section *Crisscross* agree with the relative ages of the intrusions.
- How would your answer have changed for cross section *Crisscross* if you did not have absolute age data?
- Summarize** your reasoning for establishing a relative age for fault X in the cross section *No Fault of Mine*.

Answers to Questions

- Student answers will vary.
- Cross cutting features and intrusions are most helpful.

Error Analysis Have students compare their chronologies and resolve any differences. More than one solution is possible for those cross sections with the answer statement “anytime after.”

Conclude and Apply

- Student answers will vary. The key to apply is “anytime after.”
- Absolute ages agree; relative age would not change; absolute ages are used for confirmation.
- Relative age would not change; absolute ages are to establish ages of rocks before or after intrusions.
- Fault X has to come after the youngest layer that it effects aligning the sequences on both sides of the fault reveals the same sequence G, I, J.

Assessment

Performance Ask students to draw a simple, labeled, geologic cross section that illustrates each of the relative dating principles: superposition, cross cutting, and original horizontality. Then have them create labeled drawings to illustrate a cross section of a geologic structure: basin, dome, anticline/syncline. L2

LAB 677

Communicating Your Data

Prepare an oral defense for your interpretation of one of the cross sections. Answer questions from classmates who might have made different conclusions about the same cross section.

Alternative Inquiry Lab

What was the sequence? Students can model geologic events by using different colors of clay to represent horizontal, angular, and folded rock layers. Using plastic knives and spoons to create erosion surfaces and faults. Exchange cross sections with other students and have them infer the sequence in which the original models were made.

Communicating Your Data

Have students relate their interpretation of a cross section as part of the Error Analysis process.

Content Background

Groundwater flow is a very complex, poorly understood subject. Channels underground can carry water in directions unrelated to the surface topography. Because the patterns of water distribution are not generally mapped and groundwater often travels tens or hundreds of miles from the recharge zone, disturbance of groundwater can have unexpected effects. In addition to problems of water shortage, this makes pollution of groundwater particularly problematic. Groundwater mining frequently causes the surface to subside as water is removed from the aquifer, creating structural problems to buildings as the grounds settles inches or feet per year. Also, once the water is removed, many subsurface soils become compacted by the weight of soil above. These soils cannot be recharged with fresh water, permanently destroying that part of the aquifer.

Discussion

Water Sources What other sources of water could be used in order to avoid mining groundwater? Possible answers: *streams, water collected from surface runoff in mountains; desalination of seawater; catching water that falls on roofs for use in building; recycling wastewater*

Activity

Have students measure the capacity of a large plastic or metal bowl by filling it with water from a graduated cylinder or measuring cup. Empty the bowl and fill it completely with coarse gravel. Have students add a measured amount of water to the rim of the bowl. Determine what percent of the bowl of gravel is actually open space between rocks. Several groups of students can use different sizes of gravel and compare the results.

Tapping into the Underground

Freshwater is one of our most important natural resources. Although it may seem that there is an unlimited supply of water—just turn on the faucet and there it is—water supplies can run out. Much of Earth's freshwater is stored in aquifers, inside the cracks and pores of rock and soil. Some of this water flows to the surface and is continually replaced by rainfall that filters through the ground. Other aquifers lie far below the surface, holding water that fell as rain thousands of years ago.

Humans pump water from underground for many uses including drinking, bathing, irrigating crops, and for manufacturing. Because the time needed for water to move into an aquifer can be years or even centuries, these uses consume water faster than it can be replaced by natural processes. When that happens, water is no longer a renewable resource and groundwater shortages become likely.

If water is pumped from a well faster than it can be replaced, the area around it becomes depleted. This results in wells must be drilled deeper and deeper. Eventually the water flow becomes too slow to be useful. Groundwater shortages don't just affect the amount of water, but they can also affect its quality. Under normal conditions, the direction of underground water

flow tends to be the same as the slope of the surface. As the supply is depleted, water flows from all directions toward the well. In places near the ocean, salt water flowing into the aquifer can make the water useless.

Water conservation—using less water—slows the depletion of the aquifer. This helps the supply refill naturally. Many communities are taking steps to avoid groundwater shortages. In some places, wastewater is cleaned and recycled for other uses to reduce the amount of underground water needed. Another way to use recycled wastewater is to refill the groundwater supply. Treated wastewater is either pumped back into the ground or allowed to filter back into the aquifer from constructed wetlands.

Interview Contact a local hydrologist for an interview. Before the interview, do research to determine the sources of water for your community and what happens to treated wastewater. Make a list of interview questions. Conduct the interview and write a summary.

TIME

For more information, visit
fl.gpscience.com

Research Provide time for students to discuss whether there are possible alternative sources for water supply and disposal and advantages and disadvantages of each. Ask for suggestions for reducing water usage.

Reviewing Main Ideas

Section 1 Weathering and Soil

1. Mechanical weathering reduces the size of materials. Chemical weathering creates new materials or dissolves material through chemical reactions.
2. Differential weathering causes rock that is resistant to particular climate conditions to stand out in the landscape.
3. Soil is composed of weathered rock, decaying organic matter, water, and air. Soil type depends on the nature of the material from which it forms, climate type, and location.
4. Erosion and chemical depletion of soil are global problems.

Section 2 Shaping the Landscape

1. Erosion is a set of processes that physically remove material at Earth's surface.
2. All the land area that collects water for a major river is a drainage basin.
3. In order to develop, glaciers require long periods of time in which winter snowfall exceeds summer melt. Glaciers create erosional and depositional features.
4. Erosion by wind generally is limited to particle sizes that are sand-sized or smaller.
5. Erosion by wave action on rocky coastlines leaves resistant landforms behind, such as sea stacks and arches. Beach erosion and deposition is caused partly by movement of sediment by longshore currents.

6. Mass wasting is any form of erosion driven by gravity, such as landslides and mudflows.

Section 3 Groundwater

1. Groundwater accumulates by the infiltration of surface water. Infiltration is controlled by slope of land, type of surface material and type and amount of vegetation.
2. Groundwater is stored in aquifers. The movement of groundwater in an aquifer is influenced by gravity, the structure of the aquifer, and by the porosity and permeability of the aquifer.
3. Groundwater might return to the surface naturally by springs or be brought to the surface by human-made wells.

Section 4 Geologic Time

1. Relative dating principles are used to determine the order of geologic events. Radiometric dating uses the decay of radioactive isotopes to establish a numerical age for materials.
2. Geologic maps illustrate the horizontal distribution of rock formations.

FOLDABLES Use the Foldable that you made at the beginning of this chapter to help you review Earth's erosional and depositional features.

★ FCAT Vocabulary

Match the correct vocabulary word(s) with each definition given below.

1. a rock layer that stores and transmits water
2. a means of establishing the order of events
3. region that collects water for a stream system
4. concept that the laws of nature act today as they have in the past
5. a measure of the ability of a fluid to pass through a material
6. processes of chemical or physical breakdown of a substance
7. Earth's surface covering consisting of weathered rock, decaying organic matter, water, and air
8. boundary separating the saturated zone and the unsaturated zone
9. a surface representing a period of erosion or non-deposition

Checking Concepts

10. What is a process that leaves resistant rock remaining in the landscape?
 - A) deposition
 - B) differential weathering
 - C) sediment transport
 - D) infiltration
11. Which soil horizon contains the greatest amount of organic matter?
 - A) A horizon
 - B) B horizon
 - C) C horizon
 - D) O horizon
12. Which soil horizon represents weathered bedrock?
 - A) A horizon
 - B) B horizon
 - C) C horizon
 - D) O horizon
13. Which of the following is NOT a typical soil texture component?
 - A) gravel
 - B) sand
 - C) silt
 - D) clay
14. Which of the following is formed by glaciers?
 - A) V-shaped valleys
 - B) moraines
 - C) flood plain
 - D) deltas

Use the illustration below to answer questions 11–12.

- edit existing questions and add your own questions
- build tests aligned with state standards using built-in State Curriculum Tags
- change English tests to Spanish with one mouse click and vice versa

15. Select the material that slows or stops movement of ground water.
 - A) aquifer
 - B) aquitard
 - C) water table
 - D) saturated zone
16. Select the relative principle that states: *The oldest rock layer is on the bottom.*
 - A) original horizontality
 - B) cross cutting relationships
 - C) faunal succession
 - D) superposition
17. Which time unit of the geological time scale is the shortest?
 - A) eon
 - B) epoch
 - C) period
 - D) era

Interpreting Graphic

18. Copy and complete the table below.

Radioactive Decay			
Half-lives	% Parent	% Daughter	
1	25	50	75
2	12.5	87.5	50
3	6.25	93.75	
4			

Thinking Critically

19. **Explain** why a soluble rock such as limestone can stand out as cliffs in the western United States.
20. **Infer** how water from a natural spring could become contaminated.
21. **Explain** the difference between a confined aquifer and an unconfined aquifer.

22. **Infer** why cities that draw their water from a drainage basin need to understand how surrounding land is used.
23. **Infer** why rocks or fossils that are found lying on the ground are not useful for relative dating.

Use the illustration below to answer question 24.

24. **Describe** how absolute dates from ancient lava flows could be used to determine the absolute ages of fossils.
25. **Apply** The half-life of carbon-14 is 5730 years. Explain why carbon-14 is useful for dating objects that are 75,000 years old and younger.
26. **Apply** Explain why glacial deposits made of till are often poorly drained and swampy.

Applying Math

27. Suppose an aquifer is known to be 200 km long and 75 km wide. If its average saturated thickness is 40 m and it has an average porosity of 3 percent, estimate how many cubic kilometers of water could potentially be stored in the aquifer.
28. An igneous rock sample was dated using radioactive potassium. Measurement indicates that 1/32 of the original parent potassium is left in the sample. The half-life of potassium is 1.3 billion years. How old is this igneous rock?

Thinking Critically

19. The climate is arid. With little rainfall, dissolution of carbonate rocks such as limestone is minimal.
20. The infiltration area that supplies the spring is contaminated.
21. A confined aquifer has an aquitard above and below it.
22. If contaminants are dumped or vegetation is cut away in these areas, the resulting water will enter the drainage basin in a degraded condition.
23. Loose fossils could have come from anywhere and have no direct connection to any rock.
24. Fossils found in layers between the absolutely dated lava flows must be of an age between those absolute ages.
25. If an object is 75,000 years old, 13 half-lives have elapsed. Because so little of the parent material remains, it is difficult to obtain a reliable date for objects that are older.
26. Till is poorly sorted, which means that pore spaces are few and small. Porosity is low and water does not drain well through till.

Applying Math

Math Standards

National: 1, 4, 9

Florida: MA.B.1.4.1

27. 18 km^3

28. If 1/32 of the parent isotope remains, five half-lives have elapsed. $1.3 \text{ billion years} \times 5 = 6.5 \text{ billion years}$.

Multiple Choice

1. B
2. D
3. A
4. A
5. C
6. B
7. A
8. C

Gridded Response

9. 40
10. 14,000 years
11. 20 years

Record your answers on the answer sheet provided by your teacher or on a sheet of paper.
The assessed Florida Benchmark appears above the question.

Multiple Choice

Use the illustration below to answer question 1.

1. How does mechanical weathering affect rock material?
 - A. alters chemical composition
 - B. increases rock surface area
 - C. increases rock volume
 - D. slows chemical weathering
2. Which is a mixture of weathered rock, organic matter, water, and air?
 - A. feldspar
 - B. parent material
 - C. rock rust
 - D. soil
3. Which is the dropping of sediment load?
 - A. deposition
 - B. erosion
 - C. transporting
 - D. weathering

Test-Taking Tip

Remember Never leave any answer blank.

4. Which develops as force within a stream is exerted sideways?
- A. floodplain
 - B. mouth
 - C. source
 - D. tributary

Use the illustration below to answer question 5.

- Which structural form is illustrated above?
 - anticline
 - basin
 - dome
 - syncline
 - Which is where a stream's water flows into another body of water?
 - floodplain
 - mouth
 - source
 - tributary
- SC.D.1.4.3**
- Which forms at the front of a glacier?
 - end moraine
 - ground moraine
 - lateral moraine
 - medial moraine

8. Which forms when sand is moved by wind?

A. currents
B. delta
C. dunes
D. loess

Gridded Response

Use the illustration below to answer question 9.

9. Which soil texture consists of 50 percent sand and 40 percent clay?

SCA.2.4.3

10. If the half-life of an isotope is 7,000 years and the amount of that isotope present in an igneous rock is only one-fourth of the original amount, how old is the rock?

SC.8.1.4.8

11. Soil erosion in an area is 3.0 cm per year. The soil profile is 2.4 m thick and 25 percent of that is topsoil. How long will it take for the topsoil to erode away?

Short Response

12. How does water work to cause mechanical weathering called frost wedging?
13. How does slope affect the soil horizon?
14. Why is vegetation important to the type of soil that forms?
15. What is the drainage basin of a river?
16. How does a delta form?
17. How does a bar form on the inside of a bend in a stream?
18. How does a glacier erode the land's surface?

Extended Response

Use the art below to answer question 19.

19. **PART A** How does a longshore current form?
- PART B** Explain how a longshore current affects erosion and deposition.

Short Response

12. Water enters cracks in the rocks where it then freezes. As the water freezes, it expands, forcing the cracks apart.
13. Steep slopes cause thin, poor-quality soils. As slope decreases, thicker soil horizons will develop.
14. Vegetation provides a supply of organic material for the soil.
15. All of the land area that gathers water for the river.
16. At the mouth of a stream where it empties into another body of water, sediment is deposited in a fan-shaped deposit.
17. Water flow is the slowest at the inside of a bend in a stream. When the water flow slows, sediment is deposited forming a bar.
18. A glacier acts like a bulldozer, scraping, gouging, and plucking soil and surface rocks.

Extended Response

19. **PART A:** Movement of water parallel to the shoreline is caused by the refraction of waves that approach the shoreline at an angle.
- PART B:** As water recedes from the beach, it erodes material and carries it out to sea. As the water approaches the beach at an angle, it transports and deposits that material farther downcurrent.

Rubrics

PROJECT

CRISS

Study Skills

Organize Information Main idea-detail notes help students organize content from reading

assignments. After studying solutions and chemical reactions, students use the two-column strategy. In the left column, students list a variety of acids and bases. In the right-hand column, students write pertinent details about each, such as the properties, pH, and uses.

Main Idea

Acid

Base

Detail

Properties:

- _____
- _____

pH: _____

Uses: _____

In the mid-1800s, scientists experimented with light-sensitive chemicals. They found that when paper was treated with such chemicals and then exposed to light, the resulting reaction changed the paper's color. If an object blocked some of the light, a silhouette of the object was created. One set of chemicals produced prints—called cyanotypes—of white images on a blue background. A botanist named Anna Atkins saw the potential of this process. Until that time, the only way to create pictures of plants had been to draw them. Atkins used cyanotypes to create impressions of the plants. In 1843, she published a book of cyanotype images of algae, including the two seen at lower right. It was the first book ever to be illustrated by photography. Since Atkins' time, photography has gone through many changes. But it is still a powerful tool for making images of the natural world—which includes this giant jellyfish, whose image is being captured by an underwater photographer.

unit projects

Visit unit projects at fl.gpscience.com to find project ideas and resources.
Projects include:

- **Career** Explore careers in space travel. Design a creative want-ad and work as a class to compile a mock newspaper classified section.
- **Technology** Discover what elements are used to make salts, how they are made, where they can be found, and where they are used. Create a formula for personal bath salts or salt scrubs.
- **Model** Research the Mars rovers. Design blueprints, and construct a model with moveable parts.

WebQuest *Chemistry of Fireworks* explores the chemical compounds of fireworks, what chemicals are used, and how firework displays are created.

unit projects

Career Have students explore the field of astro-geology, cosmology, aerospace engineering, or other space travel careers. Using the information they have gathered, students may design a creative want-ad advertising an employment opportunity. A class mock newspaper classified section may be compiled to share student work.

Technology Assign a specific salt to a pair of students. Using a variety of resources, have students research what elements are used to make their salt, how it is made, where it can be found, and where it is used. Some students may be interested in researching bath salts and their popularity in today's society. Salt research suggestions might include: sodium chloride (NaCl), potassium chloride (KCl), ammonium chloride (NH₄Cl), magnesium sulfate (MgSO₄), sodium sulfate (Na₂SO₄), potassium acetate (CH₃CO₂K), sodium nitrate (NaNO₃), barium sulfate (BaSO₄), copper(II) acetate (Cu(CH₃CO₂)), or ammonium sulfate ((NH₄)₂SO₄).

Model In small groups, have students research the Mars rovers. Students may design blueprints of an electronic robot including remote controls and the capability to move, scoop, and retrieve. Actual working models may be possible using donated and recycled materials.

Additional Resources Visit unit projects at fl.gpscience.com for more information, resources, and assessment rubrics.

How Are Algae & Photography Connected?

- Students are probably familiar with a specific application of the cyanotype process—blueprints. If any of their families have blueprints of their homes, have students share them with the class.
- Ask students to hypothesize how cyanotypes can be used to photocopy

something. The item to be photocopied can be placed over treated paper and then exposed to light. Tell students that this type of copying was first done in the mid-1800s.

- Tell students that they will study many such interactions of matter and energy. All chemical reactions involve energy transfer.

Section Focus Transparency Chapter 22

1 Picking Up the Pieces

Big puzzle pieces have hundreds—even thousands—of pieces. To complete the puzzle, you need to enter how each piece fits together. Size, shape, and markings all give clues as to how the pieces should be placed to make a picture.

- Where do the remaining pieces belong? How do you know?
- How might a compound and its individual elements compare to a puzzle and its pieces?

L2

Section Focus Transparency Chapter 22

2 A Crystal Nature

There are three states of matter: solid, liquid, and gas. When a substance changes from one state to another, it is called a phase change. For example, when water freezes, it changes from a liquid to a solid. This process is called crystallization. Crystals are solids with a regular, repeating arrangement of atoms or molecules. They can be found in many different forms, such as ice, salt, and sugar.

- Describe the appearance of the salt in the picture.
- What happens to salt in water? How might you recover salt from ocean water?
- How do people use salt?

L2

Section Focus Transparency Chapter 22

3 For Best Results, Add Water

Why are these workers trying to keep the concrete wet rather than letting it dry? Concrete doesn't harden because it dries. It hardens by incorporating water into its molecular structure. If there's not enough water, the concrete won't harden properly and it won't be very durable.

- How might construction be different in the desert compared to a rainy, temperate region?
- What would happen if a bag of dry concrete got a little damp? What if it got a lot wet?
- When a new sidewalk is finally dry, where does the water go?

L2

This is a representation of key blackline masters available in the Teacher Classroom Resources. See Resource Manager boxes within the chapter for additional information.

Key to Teaching Strategies

The following designations will help you decide which activities are appropriate for your students.

- L1** Level 1 activities should be appropriate for students with learning difficulties.
- L2** Level 2 activities should be within the ability range of all students.
- L3** Level 3 activities are designed for above-average students.
- ELL** ELL activities should be within the ability range of English Language Learners.

COOP LEARN Cooperative Learning activities are designed for small group work.

LS Multiple Learning Styles logos, as described on page 12T, are used throughout to indicate strategies that address different learning styles.

P These strategies represent student products that can be placed into a best-work portfolio.

PBL Problem-Based Learning activities apply real-world situations to learning.

Assessment

Assessment Transparency Chapter 22

Chemical Bonds

Directions: Read the tables and answer the following questions.

Group A		Group B	
Water	H ₂ O	Epsom salts	Mg(OH) ₂
Carbon dioxide	CO ₂	Sugar	C ₁₂ H ₂₂ O ₁₁
Ammonia	NH ₃	Lye	NaOH
Salt	NaCl	Baking soda	NaHCO ₃
Methane	CH ₄	Vinegar	C ₂ H ₄ O ₂

- The compounds in Group A are different from the compounds in Group B because only the compounds in Group A:
 - A are gases at room temperature
 - B are used in preparing food
 - C contain a metal and a nonmetal
 - D contain only two different elements
- According to the chemical formula for lye, all of the following elements are found in a lye molecule: EXCEPT
 - A hydrogen
 - B oxygen
 - C nitrogen
 - D sodium
- According to the information contained in the tables, which compound has a total number of atoms greater than 10?
 - A Baking soda
 - B Sugar
 - C Methane
 - D Vinegar
- According to the tables, which compound has the LEAST number of total atoms?
 - A Ammonia
 - B Water
 - C Carbon dioxide
 - D Hydrogen

Science Content Background

section Stability in Bonding

Atomic Stability

Atoms undergo rearrangements of electrons to become more stable. This concept forms the basis for understanding chemical bonding. The most stable configuration of electrons is found in the noble gases. Atoms gain, lose, or share electrons, some more easily than others, so that they have the same electron configurations as the noble gases. For example, a chlorine atom gains an electron (Cl^-) and attains an electron structure like the chemically stable noble gas argon. Sodium loses one of its 11 electrons (Na^+) to attain an electron structure like neon. In general, metals tend to form positively charged ions (lose electrons) and nonmetals form negatively charged ions (gain electrons).

section Types of Bonds

Electron Dot Structures

One of the most convenient ways to picture the sharing of electrons between atoms in covalent or polar covalent bonds is to use electron dot structures. Electron dot

structures are often called Lewis structures, after American chemist G. N. Lewis (1875–1946), who invented this symbolism. Electron dot structures represent an atom's outer-level, or valence, electrons by dots. Atoms form covalent bonds by sharing electron pairs, with the resulting molecules drawn by assigning the correct number of valence electrons to each atom. Group 13 atoms have three valence electrons, Group 14 atoms have four valence electrons, and so on across the periodic table.

Group 18 elements, such as neon and argon, rarely form covalent bonds because they have a stable configuration of eight electrons in their outer energy levels. This is called the octet rule—representative elements react so that they attain eight electrons in their outer energy level.

Lewis dot structures can be used to model covalent bonding and predict the number of bonds between atoms in a compound. For example, in N_2 , the atoms share three pairs of electrons. Each pair represents a bond, so N_2 has a triple bond. Multiple bonds are shorter and stronger than single bonds because there are more electrons holding the nuclei together.

Although Lewis dot structures are accurate models of bonding for most compounds, laboratory data from some compounds do not always agree with conclusions drawn from these models. This is the case with O_2 . The Lewis dot structure predicts that O_2 will contain a double bond and four electron pairs. Bond length studies have shown that the O_2 bond length is consistent with that of a double bond. However, O_2 is known to be paramagnetic (it has unpaired electrons). This apparent discrepancy has been resolved by applying quantum-based molecular orbital (MO) theory.

Barry L. Runk/Grant Heilman Photography, Inc.

Electronegativity

When two different kinds of atoms share a pair of electrons, a bond forms in which electrons are shared unequally. The attractive force that an atom of an element has for shared electrons in a molecule is known as its electronegativity. Nobel laureate Linus Pauling (1901–1994) developed a scale of relative electronegativities, in which the most electronegative element, fluorine, is assigned a value of 4.0. The higher the electronegativity, the stronger an atom attracts electrons within a bond. Electronegativity generally increases from left to right across a period and decreases down a group for typical elements.

Teacher to Teacher

Mark Resch,
Ripon High School
Ripon, Wisconsin

"I balance an 8-inch piece of 2×4 lumber on a watch glass. Then, I induce a charge in an inflated balloon by rubbing it in my hair. I hold the charged balloon to the side near one end of the 2×4 . The balloon will be attracted to the wood. I move the balloon to the other side to reverse direction. Unless the air is very humid, this will work."

Mark Resch

Polar or Nonpolar?

A general knowledge of electronegativities can be used to make predictions about bond polarity. A general guideline is that bonds between atoms with the same or similar values are nonpolar covalent, bonds between atoms whose values differ by more than 1.7 are substantially ionic, and bonds between atoms

Structure and Bonding, by Jack Barrett and Eddie Abel, Wiley, John & Sons, Incorporated, 2002

whose values differ by less than 1.7 are polar covalent. At the extreme, one or more electrons are actually transferred and an ionic bond results. It is important to realize that bonding is a continuum—the difference between ionic and covalent is a gradual change.

Writing Formulas and Naming Compounds

Hydrates

The best-known hydrates are crystalline solids that lose their structure upon removal of their bound water. Although the number of molecules of water in a given hydrate is fixed, some substances can form several different hydrates. For example, there are four different hydrates of iron (II) sulfate, each with separate and unique physical properties.

Virtual Lab: How can you tell which elements form chemical bonds?

Elements Form Chemical Bonds

Just as these skydivers are linked together to make a stable formation, the atoms in elements can link together with chemical bonds to form a compound. You will read about how chemical bonds form and learn how to write chemical formulas and equations.

Science Journal Describe how glue is similar to chemical bonds.

Theme Connection

Stability and Change The relationship between an atom's electronic structure and its stability is described in this chapter. Chemical bonding enables atoms to become stable. Chemical changes take place when existing bonds are broken and new bonds form.

About the Photo

Bond Strength Use the analogy of these skydivers gripping hands to associate bond strength with the formation of stable and unstable formations.

Start-Up Activities

Chemical Bonds and Mixing

You probably have noticed that some liquids such as oil-and-vinegar salad dressings will not stay mixed after the bottle is shaken. However, rubbing alcohol and water will mix. The compounds that make up the two liquids are different. This lab will demonstrate the influence the types of chemical bonds have on how the compounds mix.

1. Pour 20 mL of water into a 100-mL graduated cylinder.
2. Pour 20 mL of vegetable oil into the same cylinder. Vigorously swirl the two liquids together, and observe for several minutes.
3. Add two drops of food dye and observe.
4. After several minutes, slowly pour 30 mL of rubbing alcohol into the cylinder.
5. Add two more drops of food dye and observe.
6. **Think Critically** In your Science Journal, write a paragraph describing how the different liquids mixed. Would your final results be different if you added the liquids in a different order? Explain.

FOLDABLESSM Study Organizer

Chemical Formulas Every compound has a chemical formula that tells exactly which elements are present in that compound and exactly how many atoms of each element are present in that compound. Make the following Foldable to help identify the chemical formulas in this chapter.

- STEP 1** Fold a sheet of notebook paper vertically from side to side.

- STEP 2** Cut along every third line of only the top layer to form tabs.

Read and Write Go through the chapter, find ten chemical formulas, and write them on the front of the tabs. As you read the chapter, write what compound each formula represents under the appropriate tab.

Science line

Preview this chapter's content and activities at fl.qpscience.com

Purpose Use the Launch Lab to introduce students to the interaction between liquids with polar bonds and liquids with nonpolar bonds. **L2** **LS** **Visual-Spatial**

Preparation Prepare small beakers of each liquid for each group.

Materials two 100-mL graduated cylinders, water, vegetable oil, rubbing alcohol, food dye, dropper

Teaching Strategy Explain that the molecules in water, food dye, and rubbing alcohol have polar chemical bonds, but the molecules in vegetable oil have nonpolar chemical bonds.

Think Critically

When the oil was added to the water and the cylinder was shaken, the oil formed bubbles that quickly separated from the water when the cylinder was allowed to sit. The oil then formed a layer on top of the water. The drops of food dye moved through the nonpolar oil as droplets. Once the drops of food dye passed through the oil/water boundary, they mixed with the water molecules, exploding with color. The alcohol, which is polar, remained on top of the oil, and the food dye dissolved in it immediately.

Assessment

Portfolio Ask students to draw a labeled diagram of their graduated cylinder filled with liquids. Use **Performance Assessment in the Science Classroom**, p. 127.

Dinah Zike Study Fold

Student preparation materials for this Foldable are available in the **Chapter FAST FILE Resources**.

L2

Reading Preview

Tie to Prior Knowledge

Jigsaw Puzzle Have students consider how pieces of a jigsaw puzzle fit together in an orderly, exact way. Explain that it is possible to predict how atoms of different elements fit together in an exact way. As an example, discuss how water forms when two parts hydrogen combine with one part oxygen. The “parts” in this case are atoms that form chemical bonds with one another.

Content-Specific Words Ask students to create cartoons that describe each of the vocabulary words. For *ion*, students might draw an atom character giving away the letter “e,” which represents an electron.

Reading Guide

What You'll Learn

- **Describe** how a compound differs from its component elements.
- **Explain** what a chemical formula represents.
- **Explain** that the electric forces between electrons and protons, which are oppositely charged, are essential to forming compounds.
- **State** a reason why chemical bonding occurs.

Why It's Important

The millions of different kinds of matter around us are a result of chemical bonds.

Review Vocabulary

compound: substance formed from two or more elements in which the exact combination and proportion of elements is always the same

New Vocabulary

- chemical formula
- ion

Figure 1 The difference between the elemental copper metal and the copper compound formed on the Statue of Liberty is striking.

Combined Elements

Have you noticed the color of the Statue of Liberty? It is green. The Statue of Liberty is made of copper, which is an element. Uncombined, elemental copper is a bright, shiny copper color.

When copper is exposed to the weather over a long period of time, the metal combines with substances in the atmosphere and changes color.

Compounds Some of the matter around you is in the form of uncombined elements such as copper, sulfur, and oxygen. However, like many other sets of elements, these three elements can unite chemically to form a compound when the conditions are right. The green coating on the Statue of Liberty and some old pennies is a result of this chemical change. One compound in this coating, seen in contrast with the elemental copper in **Figure 1**, is a compound called copper sulfate. Copper sulfate isn't shiny and copper colored like elemental copper. Nor is it a pale-yellow solid like sulfur or a colorless, odorless gas like oxygen. It has its own unique properties.

Physical Science Critical Thinking/Problem Solving, p. 1

New Properties An observation you will make is that the compound formed when elements combine often has chemical and physical properties that aren't anything like those of the individual elements. Sodium chloride, for example, shown in **Figure 2**, is a compound made from the elements sodium and chlorine. Sodium is a shiny, soft, silvery metal that reacts violently with water. Chlorine is a poisonous greenish yellow gas. Would you have guessed that these elements combine to make ordinary table salt?

Figure 2 Sodium is a soft, silvery metal that combines with chlorine, a greenish yellow gas, to form sodium chloride, which is a white crystalline solid. **Describe** how the properties of table salt are different from those of sodium and chlorine.

Formulas

The chemical symbols Na and Cl represent the elements sodium and chlorine. When written as NaCl, the symbols make up a formula, or chemical shorthand, for the compound sodium chloride. A **chemical formula** tells what elements a compound contains and the exact number of the atoms of each element in a unit of that compound. The compound that you are probably most familiar with is H_2O , commonly known as water. This formula contains the symbols H for the element hydrogen and O for the element oxygen. Notice the number 2 written as a subscript after the H for hydrogen. *Subscript* means “written below.” A subscript written after a symbol tells how many atoms of that element are in a unit of the compound. If a symbol has no subscript, the unit contains only one atom of that element. A unit of H_2O contains two hydrogen atoms and one oxygen atom.

Look at the formulas for each compound listed in **Table 1**. What elements combine to form each compound? How many atoms of each element are required to form each of the compounds?

Table 1 Some Familiar Compounds

Familiar Name	Chemical Name	Formula
Sand	Silicon dioxide	SiO_2
Milk of magnesia	Magnesium hydroxide	$\text{Mg}(\text{OH})_2$
Cane sugar	Sucrose	$\text{C}_{12}\text{H}_{22}\text{O}_{11}$
Lime	Calcium oxide	CaO
Vinegar	Acetic acid	CH_3COOH
Laughing gas	Dinitrogen oxide	N_2O
Grain alcohol	Ethanol	$\text{C}_2\text{H}_5\text{OH}$
Battery acid	Sulfuric acid	H_2SO_4
Stomach acid	Hydrochloric acid	HCl

Reading Check

Describe what a chemical formula tells you.

Caption Answer

Figure 2 Table salt is a stable, white solid. Sodium is very reactive with water, silver in color, soft, and a metal. Chlorine is a poisonous, greenish-yellow gas.

Discussion

Similar Formulas Point out that H_2O and H_2O_2 have similar chemical formulas. Does this mean they are similar compounds? Explain. They are not similar compounds. The addition of one oxygen atom changes H_2O (water), a substance that is critical for life, into H_2O_2 (hydrogen peroxide), a substance that is used as a disinfectant and quickly reacts with many other compounds.

L1 **Logical-Mathematical**

Text Question Answer

sand: 1 atom of silicon (Si), 2 of oxygen (O); milk of magnesia: 1 atom of magnesium (Mg), 2 of oxygen (O), 2 of hydrogen (H); cane sugar: 12 atoms of carbon (C), 22 of hydrogen (H), 11 of oxygen (O); lime: 1 atom (ion) of calcium (Ca), 1 of oxygen (O); vinegar: 2 atoms of carbon (C), 2 of oxygen (O), and 4 of hydrogen (H); laughing gas: 2 atoms of nitrogen (N), 1 of oxygen (O); grain alcohol: 2 atoms of carbon (C), 6 of hydrogen (H), 1 of oxygen (O); battery acid: 2 atoms of hydrogen (H), 1 of sulfur (S), 4 of oxygen (O); stomach acid: 1 atom of hydrogen (H), 1 of chlorine (Cl) **L2**

L3 **Logical-Mathematical**

Reading Check

Answer tells what elements are present in a compound and the exact number of the atoms of each element in a unit of that compound

Reading Strategy

Preview Prior to reading, ask students to scan the text. remind them to notice figures and bold print. Provide discussion prompts such as the following, to heighten interest: What does H_2O represent, and why do we use symbols?

Visual Learning

Figure 3 Have students predict whether each atom shown would more likely gain or lose electrons to form an octet. An atom with fewer than four electrons in the outer energy level tends to give up electrons, while those with more than four tend to gain electrons to form an octet. **L1 Visual-Spatial**

	1	2	13	14	15	16	17	18
2	Li	Be	B	C	N	O	F	Ne
3	Na	Mg	Al	Si	P	S	Cl	Ar

Figure 3 The number of electrons in each group's outer level increases across the table until the noble gases in Group 18, where each has a complete outer energy level.

Atomic Stability

Why do atoms form compounds? The electric forces between electrons and protons, which are oppositely charged, hold atoms and molecules together, and thus they are the forces that cause compounds to form. The periodic table on the inside back cover of your book lists the known elements. However, the six noble gases in Group 18 do not form compounds, or do so with difficulty. Atoms of noble gases are unusually stable. Compounds of these atoms rarely form because they are almost always less stable than the original atoms.

The Unique Noble Gases To understand the stability of the noble gases, it is helpful to look at electron dot diagrams across a period. Electron dot diagrams show only the electrons in the outer energy level of an atom. They contain the chemical symbol for the element surrounded by dots representing its outer electrons. How do you know how many dots to make? For Groups 1 and 2 and 13 through 18, you can use the periodic table or the portion of it shown in **Figure 3**. Elements in Group 1 each have one outer electron. Those in Group 2 each have two. Those in Group 13 each have three, those in Group 14, four, and so on to Group 18, the noble gases, which each have eight.

Chemical Stability An atom is chemically stable when its outermost energy level has the maximum number of electrons. The outer energy levels of helium and hydrogen are stable with two electrons. The outer energy levels of all the other elements are stable when they contain eight electrons. **Figure 4** shows electron dot diagrams of some of the noble gases. Notice that eight dots surround Kr, Ne, Xe, Ar, and Rn, and two dots surround He.

Figure 4 Electron dot diagrams of noble gases show that they each have a stable outer energy level.

He	Kr
Ne	Xe
Ar	Rn

690 CHAPTER 22 Chemical Bonds

Use an Analogy

Gloves In a cold climate, each person would seek to have two gloves to keep his or her hands warm. Someone with fewer than two would try to get warm by gaining a glove or two. A person with more than two gloves might give up those not needed for warmth. Individuals with exactly two gloves would not be involved in any rearrangements. Similarly, some atoms give up electrons to have eight in their outer energy levels, while others must obtain electrons to have eight. An atom with exactly eight electrons in its outer level does not need to gain or lose electrons, so it does not participate in rearrangements of electrons between atoms. The atoms of all the nonreactive noble gases except helium have eight electrons in their outer energy levels. Helium's outer level is complete with two electrons.

Activity

Binary Compounds Have the students create binary compounds using the periodic chart. Then have the student research that compound and describe it to the other students.

Caption Answer

Figure 5 Group 18

Reading Check

Answer Helium has a full outer energy level and is chemically stable.

Teacher FYI

New Elements The number of known elements may change during your use of this text. Research teams in Dubna, Russia; Darmstadt, Germany; and Berkeley, California are working to synthesize new elements.

Differentiated Instruction

Challenge Some students will wonder why the text skips elements in Group 3 to Group 12 when talking about outer-level electrons. Encourage these students to research and write brief reports about why these transition metals are skipped. The outer energy levels of these elements are similar to those of elements in Groups 1 or 2. As electrons are added, they fill in incomplete lower electron energy levels. **L3 L Linguistic**

Energy Levels and Other Elements How do the dot diagrams represent other elements, and how does this relate to their ability to make compounds? Hydrogen and helium, the elements in period 1 of the periodic table, can hold a maximum of two electrons in their outer energy levels. Hydrogen contains one electron in its lone energy level. A dot diagram for hydrogen has a single dot next to its symbol. This means that hydrogen's outer energy level is not full. It is more stable when it is part of a compound.

In contrast, helium's outer energy level contains two electrons. Its dot diagram has two dots—a pair of electrons—next to its symbol. Helium has a full outer energy level and is chemically stable. Helium rarely forms compounds and the element is a commonly used gas.

When you look at the elements in Groups 13 through 17, you see that none of the elements has a stable energy level. Each group contains too few electrons for a stable level of eight electrons.

Reading Check Why is it rare for helium to form a compound?

Outer Levels—Getting Their Fill As you just learned, hydrogen is an element that does not have a full outer energy level. How does hydrogen, or any other element, become stable? Atoms with partially stable outer energy levels can lose, gain, or share electrons to obtain stable outer energy levels. They do this by combining with other atoms that also have partially complete outer energy levels. As a result, each becomes stable. **Figure 5** shows electron dot diagrams for sodium and chlorine. When they combine, sodium loses one electron and chlorine gains one electron. You can see from the electron dot diagram that chlorine now has a stable outer energy level, similar to a noble gas. But what about sodium?

Scienceonline

Topic: Dot Diagrams

Visit fl.gpscience.com for Web links to information about using dot diagrams to represent outer energy level electrons.

Activity Draw a dot diagram of methane, CH_4 .

Figure 5 Sodium, as a Group 1 element, will lose one electron. It will have the same number of electrons as neon. Chlorine, which belongs to Group 17, will gain one electron. It will have the same number of electrons as argon. **Identify** the group number where neon and argon can be found.

SECTION 1 Stability in Bonding 691

Quick Demo

Chemical Reactions

Materials calcium metal, 1 M HCl, beaker

Estimated Time 10 minutes

Safety Precautions

Procedure Place a pea-sized piece of calcium metal in a small amount of 1 M HCl. Have students note the production of bubbles as H_2 is given off. Carefully evaporate the liquid, leaving CaCl_2 . On the board, write the dot diagram for the ions contained in this ionic compound. **Both Ca^{2+} and Cl^- contain eight outer electrons.** (If zinc metal is used instead of Ca, ZnCl_2 will form.) **L2 ELL** **Visual-Spatial**

Make a Model

Elements Have students use various colors of modeling clay to make spheres that represent metals and nonmetals. Tell them to use smaller spheres of a specific color to show electrons. Attach the correct number of electrons to each model sphere to represent the outer energy level of the selected atoms. Challenge students to use a periodic table to identify possible elements that each model represents. Then have them explain how the element in each model can obtain eight outer electrons through various combinations with other elements. **L2 ELL**

Kinesthetic

Text Question Answer

Its outer level is filled, too.

Differentiated Instruction

Learning Disabled Prepare physical models of various atoms and have the students assemble them. Then they can see how the electrons are essential to forming stable chemical bonds between atoms.

Challenge Use dot diagrams with one carbon atom and two oxygen atoms to make an arrangement that gives the carbon and oxygen atoms an octet. **Place carbon in the center and make double bonds between the carbon and oxygen atoms. In this arrangement, the carbon atom shares two electrons with one oxygen atom and two with the other. Each oxygen atom shares two electrons with the carbon atom.** **L3** **Visual-Spatial**

Fun Fact

The minimum amount of energy needed to remove the outermost (highest energy) electron from a neutral atom in the gaseous state is referred to as the first ionization potential.

Post Reading

Fix-Up Strategy Choose a challenging piece of text and read it aloud while interjecting questions and strategies to aid comprehension. Show students how to use reflat figures to help unlock the text. Then, have students find their own difficult passage and practice close reading with a partner.

3 Assess

DAILY INTERVENTION

Check for Understanding

Logical-Mathematical Have students review the periodic table and identify which groups would most likely form binary compounds with each other. Then have them give examples of some of the possible binary compounds and draw the dot diagrams of each one.

Reteach

Electron Distribution Remind students that giving up electrons can sometimes provide a new outer level of eight electrons. Make a poster with sodium's electron distribution written out—two in the first level, eight in the second. Loosely tape a page with the single electron in the third energy level written on it over the poster. Demonstrate that when the outer page is removed (losing the electron), the new outer level is shown to contain eight electrons. **L1**

ELL **LS** Visual-Spatial

Figure 6 In water, hydrogen and oxygen each contribute one electron to each hydrogen-oxygen bond. The atoms share those electrons instead of giving them up.

Stability Is Reached Sodium had only one electron in its outer energy level, which it lost when it combined with chlorine to form sodium chloride. However, look back to the next, outermost energy level of sodium. This is now the new outer energy level, and it is stable with eight electrons. When the outer electron of sodium is removed, a complete inner energy level becomes the new outer energy level. Sodium and chlorine are stable now because of the exchange of an electron.

In the compound water, each hydrogen atom needs one electron to have a stable outer energy level. The oxygen atom needs two electrons for its outer level to be stable with eight electrons. Hydrogen and oxygen become stable and form bonds in a different way from sodium and chlorine. Instead of gaining or losing electrons, they share them. **Figure 6** shows how hydrogen and oxygen share electrons to achieve a more stable arrangement of electrons.

Atoms, too, lose or gain to meet a goal—a stable energy level. They do not lose or gain an advantage. Instead, they lose or gain electrons. An atom that has lost or gained electrons is called an ion. An **ion** is a charged particle because it now has either more or fewer electrons than protons. The positive and negative charges are not balanced. It is the electric forces between oppositely charged particles, such as ions, that hold compounds together.

section 1 review

Summary

Combined Elements

- When elements combine, the new compound has unique properties that are different from the original properties of the elements.

Formulas

- Chemical symbols and numbers are shorthand for the elements and their amounts in chemical formulas.

Atomic Stability

- The elements of Group 18, the noble gases, rarely combine with other elements.
- Electron dot diagrams show the electrons in the outer energy level of an atom.
- Most atoms need eight electrons to complete their outer energy levels.

Self Check

- Compare and contrast** the properties of the individual elements that combine to make salt with the compound salt.
- Identify** what the formula BaF_2 tells you about this compound.
- Explain** why some elements are stable on their own while others are more stable in compounds.
- Think Critically** The label on a box of cleanser states that it contains CH_3COOH . What elements are in this compound? How many atoms of each element can be found in a unit of CH_3COOH ?

Applying Math

- Use Percentages** Given that the molecular weight of $\text{Mg}(\text{OH})_2$, magnesium hydroxide, is 58.32 g, what percentage of this compound is oxygen?

Assessment

Performance Have students write out the dot diagrams for two atoms of aluminum and for three atoms of oxygen. Then have them show how this combination gives all atoms eight outer, shared electrons. Use PASC, p. 127.

section 1 review

- Sodium, as an element, is a solid metal. Chlorine is a gas. When the two combine to form sodium chloride, they form a solid compound.
- The compound ratio is made up of one barium ion and two fluoride ions. Also, since the compound is made up of a metal and a nonmetal, it is likely ionic.
- If an element has eight electrons in its outer energy level, it has a tendency not to react because the element is stable. Other elements form compounds as a way to complete their outer energy levels in order to become stable.
- Hydrogen, carbon, and oxygen are in the compound. Each unit contains four hydrogen, two carbon, and two oxygen atoms.
- 54.86%

MA.A.1.4.4

Atomic Trading Cards

Perhaps you have seen or collected trading cards of famous athletes. Usually, each card has a picture of the athlete on one side with important statistics related to the sport on the back. Atoms also can be identified by their properties and statistics.

Real-World Problem

How can a visible model show how energy levels fill when atoms combine?

Goals

- **Display** the electrons of elements according to their energy levels.
- **Compare and classify** elements according to their outer energy levels.

Materials

4-in $\times$ 6-in index cards
periodic table

Procedure

1. You will get an assigned element from your teacher. Write the following information for your element on your index card: name, symbol, group number, atomic number, atomic mass, and metal, nonmetal, or metalloid.
2. On the other side of your index card, show the number of protons and neutrons in the nucleus (e.g., $6p$ for six protons and $6n$ for six neutrons for carbon).
3. Draw circles around the nucleus to represent the energy levels of your element. The number of circles you will need is the same as the period the element is in on the periodic table.

4. Draw dots on each circle to represent the electrons in each energy level. Remember, elements in row 1 become stable with two outer electrons, while levels two and three become stable with eight electrons.
5. Look at the picture side only of four or five of your classmates' cards. Identify the element and the group to which it belongs.

Conclude and Apply

1. As you classify the elements according to their group number, what pattern do you see in the number of electrons in the outer energy levels?
2. Atoms that give up electrons combine with atoms that gain electrons to form compounds. In your Science Journal, predict some pairs of elements that combine in this way.

Communicating Your Data

Make a graph that relates the groups to the number of electrons in their outer energy levels. **For more help, refer to the Science Skill Handbook.**

LAB 693

Real-World Problem

Purpose Students make models showing the number of electrons in the outer energy levels of atoms of various elements and compare and classify those elements. **L2 Visual-Spatial**

Process Skills formulate models, classify, use numbers, compare and contrast, make and use graphs

Time Required 40 minutes

Procedure

Teaching Strategy To avoid confusion, assign elements from Groups 1, 2, and 13–18 only.

Troubleshooting Emphasize to students that the circles around the nucleus are only representations of the energy levels of electrons. Electrons do not actually move in circles.

Conclude and Apply

1. They are the same in each group.
2. Sodium and potassium give up the only electron in their respective outer energy levels to chlorine and iodine, forming the chemically stable compounds sodium chloride and potassium iodide.

Assessment

Oral Ask students to which group carbon and silicon belong and whether these two elements are more likely to gain electrons, lose electrons, or share electrons when they form compounds. **Group 14; because they have four electrons in their outer energy levels they most likely share electrons.** Use **Performance Assessment in the Science Classroom**, p. 89.

Communicating Your Data

Have students enter the number of electrons in the outer energy levels of atoms and the numbers of the groups to which the atoms belong in a computer spreadsheet. Then have them use the spreadsheet's graphing function to make the graph.

Types of Bonds

Motivate

An editable Microsoft® PowerPoint® presentation is available on Interactive Chalkboard CD-ROM.

Bellringer

Section Focus Transparencies also are available on the Interactive Chalkboard CD-ROM.

L2 ELL

Section Focus Transparency A Crystal Nature

This picture shows salt crystals on the Dead Sea shore. When a salt crystal is pure, it is in the shape of a colorless cube. Impurities can make salt appear to be different colors, like white or gray. Table salt is a compound of sodium and chlorine.

- Describe the appearance of the salt in the picture.
- What happens to salt in water? How might you recover salt from ocean water?
- How do people use salt?

L2

Tie to Prior Knowledge

Electrolytes Ask students if they have ever consumed sports drinks. Explain that the electrolytes that are advertised to be in sports drinks are ions that are found naturally in human blood.

Word Associations Ask students to associate new vocabulary terms with related words. For example, *chemical bond* might be associated with *link*. Have students brainstorm associations and write them on the board.

Reading Guide

FCAT Vocabulary

What You'll Learn

- **Describe** ionic bonds and covalent bonds.
- **Identify** the particles produced by ionic bonding and by covalent bonding.
- **Distinguish** between a nonpolar covalent bond and a polar covalent bond.

Why It's Important

Bond type determines how compounds mix and interact with other compounds.

Review Vocabulary

atom: the smallest particle of an element that still retains the properties of the element

New Vocabulary

- chemical bond
- ionic bond
- **covalent bond**
- **molecule**
- polar molecule
- nonpolar molecule

Gain or Loss of Electrons

You and a friend decide to go to the movies. When you arrive at the theater, you discover that you do not have enough money to buy a ticket. Your friend has enough money for both tickets and loans you the money. Now you both have enough money to go to the movies.

Recall that atoms also can loan electrons to other atoms so that both can reach a stable energy level. When atoms gain, lose, or share electrons, an attraction forms that pulls the atoms together to form a compound. This attraction is called a chemical bond. A **chemical bond** is the force that holds atoms together in a compound. A compound has different physical and chemical properties from those of the atoms that make up the compound.

Some of the most common compounds are made by the loss and gain of just one electron. These compounds contain an element from Group 1 on the periodic table and an element from Group 17. Some examples are sodium chloride, commonly known as table salt, and potassium iodide, an ingredient in iodized salt.

Why do people need iodized salt? A lack of iodine causes a wide range of problems in the human body. The most obvious is an enlarged thyroid gland, as shown in **Figure 7**, but the problems can include mental retardation, neurological disorders, and physical problems.

Figure 7 A goiter, an enlargement of the thyroid gland in the neck, can be caused by iodine deficiency.

A Bond Forms What happens when potassium and iodine atoms collide? A neutral atom of potassium has one electron in its outer level. This is not a stable outer energy level. When potassium forms a compound with iodine, potassium loses one electron from its fourth level, and the third level becomes the complete outer level. However, the atom is no longer neutral. The potassium atom has become an ion. When a potassium atom loses an electron, the atom becomes positively charged because there is one electron less in the atom than there are protons in the nucleus. The $1+$ charge is shown as a superscript written after the element's symbol, K^+ , to indicate its charge. *Superscript* means “written above.”

The iodine atom in this reaction undergoes change as well. An iodine atom has seven electrons in its outer energy level. Recall that a stable outer energy level contains eight electrons. During the reaction with potassium, the iodine atom gains an electron, leaving its outer energy level with eight electrons. This atom is no longer neutral because it gained an extra negative particle. It now has a charge of $1-$ and is called an iodide ion, written as I^- . The compound formed between potassium and iodine is called potassium iodide. The dot diagrams for the process are shown in **Figure 8**.

Reading Check

What part of an ion's symbol indicates its charge?

Another way to look at the electron in the outer shell of a potassium atom is as an advertisement to other atoms saying, “Available: One electron to lend.” The iodine atom would have the message, “Wanted: One electron to borrow.” When the two atoms get together, each becomes a stable ion. Notice that the resulting compound has a neutral charge because the positive and negative charges of the ions cancel each other.

Ions and Nerve Cells

Ions are important in many processes in your body. The movement of muscles is just one of these processes. Muscle movement would be impossible without the movement of ions in and out of nerve cells.

Research the type of ions used by the nerve cells.

Figure 8 Potassium and iodine must perform a transfer of one electron. Potassium and iodine end up with stable outer energy levels. **Infer** why the size of the ion changes with the change in electron distribution.

2 Teach

Reading Check

Answer the superscript written after the element's symbol

Ions and Nerve Cells The primary ions needed for nerve impulses are Na^+ and K^+ . Remind students that the properties of an ion of an element are different from those of the neutral atom. For example, both sodium and potassium metals react violently with water, while their ions do not.

Discussion

Atom Identity How many protons and electrons are in an atom of chlorine? **17 protons and 17 electrons** How many protons and electrons are in a common ion of Cl? **17 protons and 18 electrons** Remind students that while atoms gain or lose electrons fairly easily, changing the number of protons changes the identity of the atom. **L2 IS Logical-Mathematical**

Caption Answer

Figure 8 An ion has fewer electrons. The attraction between the positive nucleus and the electrons become greater.

Content Background

Iodine, as well as other elements such as copper and iron, is necessary to have a healthy body. These elements, which are called trace minerals, regulate many chemical reactions in the body.

Visual Learning

Figure 8 Have students find potassium and iodine on the periodic table. How many electrons does potassium have? **19** How many does iodine have? **53** Have students count the electrons in each atom and ion in **Figure 8**. Explain that the first energy level in any atom can contain up to 2 electrons, the second level can contain up to 8 electrons, the third level can contain up to 18 electrons, and the fourth level can contain up to 32 electrons. **L3 IS Visual-Spatial**

Differentiated Instruction

Learning Disabled Provide students with two bar magnets. Have them use the magnets to determine that opposite ends (charges) of the magnets attract and like ends (charges) repel. Relate this concept to the attractions that bring opposite ions together. **L1 IS Kinesthetic**

Discussion

Electron Moves Explain to students that a metal may give up an electron when forming an ionic bond. What type of charge does the metal have after it loses an electron? **positive** [L1]

Logical-Mathematical

Activity

Ionic Bonds Using a classroom periodic table, or the one in the textbook, point out potassium (K) on the left of the table. Ask a volunteer to name a nonmetal that would likely form an ionic bond with that element. **Possible answers: O or F (K_2O ; KF)** Repeat with barium (Ba). **Possible answers: Cl or S ($BaCl_2$; BaS)** Use this exercise to point out that the metals and nonmetals that form ionic bonds often are located far apart on the periodic table. [L2] **Logical-Mathematical**

Fun Fact

Most ionic compounds are soluble in water, but are not soluble in nonpolar solvents.

Quick Demo

Conductivity in Salt

Materials 9-volt battery, two insulated copper wires, flashlight bulb, salt, distilled water, one beaker

Estimated Time 15 minutes

Procedure Pour distilled water into beaker. Connect one wire to positive pole of battery and put other end in one side of beaker into water. Run another wire from negative pole of battery to flashlight bulb and another wire from bulb to water at other end of beaker. After students see that bulb does not light up, add salt to beaker and stir water to dissolve salt, bulb should then light up if enough salt is added.

Figure 9 This sparkler contains iron, which burns in air to produce an ionic compound that contains iron and oxygen.

The Ionic Bond

When ions attract in this way, a bond is formed. An **ionic bond** is the force of attraction between the opposite charges of the ions in an ionic compound. In an ionic bond, a transfer of one or more electrons takes place. With this transfer of electrons to form an ionic compound, a large amount of energy is released, as shown in **Figure 9**.

Now that you have seen how an ionic bond forms when one electron is involved, see how it works when more than one electron is involved. The formation of magnesium chloride, $MgCl_2$, is another example of ionic bonding. When magnesium reacts with chlorine, a magnesium atom loses two electrons and becomes a positively charged ion, Mg^{2+} . At the same time, two chlorine atoms gain one electron each and become negatively charged chloride ions, Cl^- . In this case, a magnesium atom has two electrons to lend, but a single chlorine atom needs to borrow only one electron. Therefore, it takes two chlorine atoms, as shown in **Figure 10**, to take the two electrons from the magnesium ion to form the compound magnesium chloride.

Zero Net Charge The result of this bond is a neutral compound. The compound as a whole is neutral because the sum of the charges on the ions is zero. The positive charge of the magnesium ion is equal to the negative charge of the two chloride ions. In other words, when different atoms form an ionic compound, electrons move from one atom to a different atom, but the overall number of protons and electrons of the combined atoms remains equal and unchanged. Therefore, the compound is neutral.

Metals and nonmetals usually combine by forming ionic bonds. Looking at the periodic table, you will see that the elements that bond ionically are often across the table from each other. Ionic compounds are often crystalline solids with high melting points.

Figure 10 A magnesium atom gives an electron to each of two chlorine atoms to form $MgCl_2$.

Teacher FYI

Ion Attraction A positive ion is always smaller than its original neutral atom, and a negative ion is always larger than its original neutral atom. The charge on an ion acts as though it were located exactly in the center of the ion. Therefore, large ions have less attraction toward other ions; the center of charge is

farther away. The more highly charged an ion is, the stronger the force around it. The strongest attractions take place between small, highly charged ions such as Al^{3+} and highly negative ions such as O^{2-} . Large, singly charged ions such as K^+ and I^- have less attractive force between them.

Sharing Electrons

Some atoms of nonmetals are unlikely to lose or gain electrons. For example, the elements in Group 14 of the periodic table have four electrons in their outer levels. They would have to either gain or lose four electrons to have a stable outer level. Losing four electrons takes a great deal of energy. Each time an electron is removed, the nucleus holds the remaining electrons even more tightly. These atoms become more chemically stable by sharing electrons, rather than by losing or gaining electrons.

The attraction that forms between atoms when they share electrons is known as a **covalent bond**. A neutral particle that forms as a result of electron sharing is called a **molecule**, as shown in **Figure 11**.

Single Covalent Bonds A single covalent bond is made up of two shared electrons. Usually, one of the shared electrons comes from one atom in the bond and the other comes from the other atom in the bond. A water molecule contains two single bonds. In each bond, a hydrogen atom contributes one electron to the bond, and the oxygen atom contributes the other. The two electrons are shared, forming a single bond. The result of this type of bonding is a stable outer energy level for each atom in the molecule.

Multiple Bonds A covalent bond also can contain more than one pair of shared electrons. An example of this is the bond in nitrogen (N_2), shown in **Figure 12**. A nitrogen atom has five electrons in its outer energy level and needs three more electrons to become stable. It does this by sharing three of its electrons with another nitrogen atom. The other nitrogen atom also shares three of its electrons. When each atom contributes three electrons, they share six electrons, or three pairs of electrons. Each pair of electrons represents a bond. Therefore, three pairs of electrons represent three bonds, or a triple bond. Each nitrogen atom is stable with eight electrons in its outer energy level. In a similar way, a bond that contains two shared pairs of electrons is a double bond. Carbon dioxide is an example of a molecule with double bonds.

Covalent bonds form between nonmetallic elements. These elements are close together in the upper right-hand corner of the periodic table. Many covalent compounds are liquids or gases at room temperature.

Figure 11 Each of the pairs of electrons between the two hydrogens and the oxygen is shared as each atom contributes one electron to the pair to make the bond.

Figure 12 The dot diagram shows that the two nitrogen atoms in nitrogen gas share six electrons.

Explain which of these gases would require the most energy to react with another element to form a compound, H_2 or N_2 .

Activity

Bond Types Point out that in general the closer together reacting elements are on the periodic table, the more likely it is that they will share electrons with one another rather than form ionic bonds. Have students use this information to predict the type of bond that will form between carbon and oxygen. **covalent** Have them predict the type of bond formed between each of the following: sodium and oxygen, **ionic**; phosphorus and oxygen, **covalent**; magnesium and oxygen, **ionic**; aluminum and oxygen, **ionic**; chlorine and oxygen, **covalent**; sulfur and oxygen, **covalent**. **L2 LS Logical-Mathematical**

Inquiry Lab

Energy Levels

Purpose to familiarize students with the energy levels of elements

Possible Materials periodic table of elements

Estimated Time 30 minutes

Teaching Strategy Assign students to groups and give each group a different element from the periodic table. Then, have students sketch their element and its various energy levels to represent electrons making up those levels. Have students brainstorm questions about elements. Allow them to explore these questions as time allows.

For additional inquiry activities, see Science Inquiry Lab Manual.

Caption Answer

Figure 12 N_2

Differentiated Instruction

English-Language Learners Use the dot diagrams to explain how atoms form covalent bonds in order to complete their outer electron energy level. Explain that the more covalent bonds that a compound has, the more energy that is required to separate the atoms with these bonds. **Visual-Spatial**

Science Journal

Dot Diagrams Have students research the work of American chemist Gilbert N. Lewis and write short paragraphs in their Science Journals about his contribution to dot diagrams. The diagrams are called **Lewis diagrams** because he developed the idea as a way of explaining attractions besides ionic bonding between atoms. The dots allowed him to better explain bonding to his students. **L2 LS Linguistic**

Mini LAB

Purpose Students observe that water molecules are polar. [L2]

Kinesthetic

Materials water faucet, balloon, wool

Teaching Strategy Practice to determine the amount of static charge that can be built up on the balloon. High humidity reduces the buildup, causing a smaller deflection of the water stream.

Analysis

1. The balloon acquires a charge when rubbed against the wool. When brought near a thin stream of water, the charge attracts water, causing the stream to bend.
2. In both cases, opposites attract. A water molecule contains a negative region and a positive region that are similar to the opposite poles of a magnet.

Assessment

Oral Explain to students that pentane (C_5H_{12}) is a nonpolar molecule. Ask students to predict whether a stream of pentane would bend if they used the same procedure followed in the MiniLAB. **No; pentane is nonpolar and therefore will not be attracted to the static charge on the balloon.** Use **Performance Assessment in the Science Classroom**, p. 89.

[L2] **Logical-Mathematical**

Caption Answer

Figure 13 Chlorine atoms have a stronger attraction for electrons than hydrogen atoms.

Mini LAB

Observing a Bond Type

Procedure

1. Turn on the faucet to produce a thin stream of water.
2. Rub an inflated balloon with wool or fur.
3. Bring the balloon near the stream of water, and describe what you see.

Analysis

1. Explain your observations.
2. Relate the attraction between the balloon and the water to the attraction between the north and south poles of two magnets. Why might water act like a magnet?

Unequal Sharing Electrons are not always shared equally between atoms in a covalent bond. The strength of the attraction of each atom to its electrons is related to the size of the atom, the charge of the nucleus, and the total number of electrons the atom contains. Part of the strength of attraction has to do with how far the electron being shared is from the nucleus. For example, a magnet has a stronger pull when it is right next to a piece of metal rather than several centimeters away. The other part of the strength of attraction has to do with the size of the positive charge in the nucleus. Using a magnet as an example again, a strong magnet will hold the metal more firmly than a weak magnet will.

One example of this unequal sharing is found in a molecule of hydrogen chloride, HCl, which is shown in **Figure 13**. In water, HCl is hydrochloric acid, which is used in laboratories and in industry to clean metal, and is found in your stomach, where it helps to digest food. Chlorine atoms have a stronger attraction for the shared electrons than hydrogen atoms do. As a result, the shared electrons in hydrogen chloride will spend more time near the chlorine atom than near the hydrogen atom. The chlorine atom has a partial negative charge, represented by a lowercase Greek symbol δ^- . The hydrogen atom has a partial positive charge, represented by a δ^+ .

Reading Check

What determines the strength of attraction of an atom?

Tug-of-War You might think of a covalent bond as the rope in a tug-of-war, and the shared electrons as the knot in the center of the rope. **Figure 14** illustrates this concept. Each atom in the molecule attracts the electrons that they share. However, sometimes the atoms aren't the same size.

The same thing happens in tug-of-war. Sometimes one team has more people or stronger participants than the other. When this is true, the knot in the middle of the rope ends up closer to the stronger team. Similarly, the electrons being shared in a molecule are held more closely to the atoms with the stronger pull or larger nucleus.

Figure 13 The chlorine atom exerts the greater pull on the electrons in hydrogen chloride, which forms hydrochloric acid in water.

Explain why the chlorine atom has a greater pull than the hydrogen atom.

698 CHAPTER 22 Chemical Bonds

Differentiated Instruction

Challenge Have students research the electronegativity scale developed by Linus Pauling and relate the information they find to the formation of covalent, polar covalent, and ionic bonds. Pauling's electronegativity scale is a way of ranking the ability of an atom to attract electrons within a bond. Two atoms that

have a small or no electronegativity difference form a covalent bond. Those with a great electronegativity difference form an ionic bond. If the difference is moderate, a polar covalent bond forms. Each element is given a numerical ranking, so simple subtraction gives the electronegativity difference. [L3]

Linguistic

Figure 14

When playing tug-of-war, if there are more—or stronger—team members on one end of the rope than the other, there is an unequal balance of power. The stronger team can pull harder on the rope and has the advantage. A similar situation exists in polar molecules, in which electrons are attracted more strongly by one type of atom in the molecule than another. Because of this unequal sharing of electrons, polar molecules have a slightly negative end and a slightly positive end, as shown below.

CHLOROFORM In a molecule of chloroform (CHCl_3), or trichloromethane (tri klor oh ME thayn), the three chlorine atoms attract electrons more strongly than the hydrogen atom does, creating a partial negative charge on the chlorine end of the molecule and a partial positive charge on the hydrogen end. This polar molecule is a clear, sweet-smelling liquid once widely used as an anesthetic in human and veterinary surgery.

HYDROGEN FLUORIDE Hydrogen and fluorine react to form hydrogen fluoride (HF). In an HF molecule, the two atoms are bound together by a pair of electrons, one contributed by each atom. However, the electrons are not shared equally because the fluorine atom attracts them more strongly than the hydrogen atom does. The result is a polar molecule with a slightly positive charge near the hydrogen end and a slightly negative charge near the fluorine end.

SECTION 2 Types of Bonds 699

Visualizing Polar Molecules

Have students examine the pictures and read the captions. Then ask the following questions.

In your own words, describe why charge is distributed unevenly in chloroform molecules. **Possible answer:** The chlorine molecules have a stronger attraction for electrons than the hydrogen molecule.

Why are the hydrogen sides of both chloroform molecules and hydrogen fluoride molecules partially positive? **The electrons have been pulled away, leaving an exposed proton in each hydrogen nucleus.**

Activity

Electron Dot Diagrams Work together as a class to draw on the board the electron dot diagrams for both molecules. Students should easily see that the electrons are concentrated on one side of each molecule, which leads to a partial negative charge on that side. Have students draw these diagrams in their Science Journals. **LS Visual-Spatial**

Differentiated Instruction

Challenge Ask students to find out what an induced dipole is. Direct students to make posters showing examples of induced dipoles and explain their posters to the class. **L3 LS Visual-Spatial P**

✓ Reading Check

Answer a molecule that has a slightly negative end and a slightly positive end

Using an Analogy

Similarities Draw an analogy between the positive and negative poles of a polar molecule and the magnetic north and south poles of Earth. Point out that one meaning of the word *polar* is “directly opposite.”

Use Science Words

Word Origin Have students use reference books to learn about the origins of various element names. Ask students to write each element symbol, name, and the source of its name. Many elements were named after countries or people. For example, polonium was named for Poland, the native land of its discoverer, Marie Curie.

Discussion

Compounds Ask students to describe various materials in the classroom and to suggest which elements make up each material. Typical responses are water—hydrogen and oxygen; metal objects—iron, aluminum, mixtures of iron with other elements, such as carbon.

Caption Answer

Figure 15 unequal sharing of electrons

Figure 15 The polarity of water is responsible for many of its unique properties.

Explain the cause of polarity.

Polar or Nonpolar? For the molecule involved in this electron tug-of-war, there is another consequence. Again, look at the molecule of hydrogen chloride. The unequal sharing of electrons gives each chlorine atom a slight negative charge and each hydrogen atom a slight positive charge. The atom holding the electron more closely always will have a slightly negative charge. The charge is balanced but not equally distributed. This type of molecule is called polar. The term *polar* means “having opposite ends.” A **polar molecule** is one that has a slightly positive end and a slightly negative end, although the overall molecule is neutral. Water is an example of a polar molecule, as shown in **Figure 15**.

✓ Reading Check What is a polar molecule?

Two atoms that are exactly alike can share their electrons equally, forming a nonpolar molecule. A **nonpolar molecule** is one in which electrons are shared equally in bonds. Such a molecule does not have oppositely charged ends. This is true of molecules made from two identical atoms or molecules that are symmetric, such as CCl_4 .

Properties of Compounds

Recall that atoms can form two types of bonds: covalent and ionic. A compound whose atoms are held together by covalent bonds is a covalent compound.

Sugar is a covalent compound. A compound that is composed of ions is an ionic compound. Table salt, NaCl , is an ionic compound. Looking at both substances, you would think they would have similar physical and chemical properties.

Both sugar and salt, as shown in **Figure 16**, are used to change the taste of foods. You add sugar to lemonade or iced tea to make the drink sweet. Table salt is used to enhance the flavors of foods, such as meats and vegetables. Sugar and salt have different physical and chemical properties.

Figure 16 Table sugar is an example of a covalent compound that is a crystalline solid soluble in water. Ionic compounds, such as table salt, are also soluble in water.

700 CHAPTER 22 Chemical Bonds

Reading Strategy

Classify Text Provide students with three key questions related to the text. Have students categorize information from the text under the key questions. A key question might be: How do different types of bonds form? Students should take notes and categorize information on ionic bonds and covalent bonds under the key question.

Figure 17 Candle wax and propane are covalent compounds that are insoluble in water.

Covalent and Ionic Properties The chemical and physical properties of covalent compounds and ionic compounds are different. This difference in properties, as shown in **Table 2**, is due to differences in attractive forces of the bonds.

Covalent Compounds The covalent bonds between atoms in molecules are strong. However, the attraction between individual molecules is weak. It is the weak forces between individual molecules that are responsible for the properties of covalent compounds.

Melting and boiling points of covalent compounds are relatively lower when compared to ionic compounds. Sugar will melt at approximately 185°C, whereas table salt will melt at 801°C. Covalent compounds, which will form soft solids, have poor electrical and thermal conductivity. Candles and propane gas shown in **Figure 17** are covalent compounds.

Table 2 Comparison of Covalent and Ionic Compounds

	Covalent Compounds	Ionic Compounds
Bond Type	Electron Sharing	Electron Transfer
Melting and Boiling Points	Lower	Higher
Electrical Conductivity	Poor	Good
State at Room Temperature	Solid, liquid, or gas	Solid
Forces Between Particles	Strong bonds between atoms; weak attraction between molecules	Strong attraction between positive and negative ions

SECTION 2 Types of Bonds **701**

Cultural Diversity

Salt of the Earth Salt has been recognized as an important and essential substance in all cultures for thousands of years. One of the major uses of salt in all parts of the world is as a preservative. Salt is used to symbolize fidelity and permanence of rela-

tionships in many societies. The Hebrew expression “to eat the salt of the palace” means to think highly of someone, just as the English phrase describing a person as “salt of the earth.”

IDENTIFYING Misconceptions

Water Students probably believe that water is an electrolyte that conducts electricity. Point out that what we call “water” is usually a solution containing small amounts of dissolved molecules and ions. The ions act as electrolytes, which allow the solution to conduct electricity.

Virtual Labs

Bonding How can you tell which elements form chemical bonds?

Post Reading

Illustrations Have students develop pictures to show ionic and covalent bonding. Allow them to creatively personify characters representing bonding atoms. Ask them to choose a particular compound, such as salt, to represent in the illustrations. Allow students to work in pairs or groups to encourage deeper understanding.

✓ Reading Check

Answer Ionic bonding causes brittleness.

3 Assess

DAILY INTERVENTION

Check for Understanding

Interpersonal Assign students to groups and have them develop a brief presentation for the class explaining the differences between polar and nonpolar molecules.

Reteach

Identify Compounds List the formulas for HCl, H₂O, NaCl, and MgCl₂ on the board. Have students identify each compound as ionic or covalent. HCl, covalent; H₂O, covalent; NaCl, ionic; MgCl₂, ionic.

L2 **IS** Logical-Mathematical

✓ Assessment

Performance Have each student write the symbol of one of the first 30 elements on a sheet of paper. Now have the student use the periodic table to try to find an element that would form a covalent bond with the first element. Have students repeat the exercise for an ionic compound and explain their choices. Emphasize that both electron configuration and attraction for electrons determine whether two atoms will bond with each other. Use **PASC**, p. 93.

Figure 18 Some common ionic compounds used in everyday life are potassium chloride as a salt substitute; potassium iodide added to table salt; and sodium fluoride added to toothpaste.

Ionic Compounds The ionic bonds between ions are relatively strong. This accounts for the high melting and boiling points of ionic compounds such as table salt. Examples of common ionic compounds are shown in **Figure 18**. Ionic compounds are hard and brittle. When in a liquid or aqueous state, ionic compounds can conduct electric current.

Strong attractive forces hold the ions in place. Ionic compounds are stable due to the attraction between unlike charges. The ions are drawn together and energy is released. Formation of ionic compounds is always exothermic.

✓ Reading Check Why are ionic compounds brittle?

section 2 review

Summary

Gain or Loss of Electrons

- An ion is a charged particle that has either fewer or more electrons than protons, resulting in a negative or positive charge.

Ionic Bond

- An ionic bond is the force or attraction between opposite charges of ions in an ionic bond.
- An ionic compound is neutral because the sum of the ion charges is zero.

Sharing Electrons

- Some atoms, such as those in Group 4, share electrons instead of losing or gaining them.
- Covalent bonds can form single, double, or triple bonds.
- In a polar molecule, the electrons are shared unequally in the bond. This results in slightly charged ends.
- Electrons are shared equally in a nonpolar molecule.

Self Check

1. **Explain** why an atom makes an ionic bond only with certain other atoms.
2. **Compare and contrast** the possession of electrons in ionic and covalent bonds.
3. **Name** the types of particles formed by covalent bonds.
4. **Concept Map** Using the following terms, make a network-tree concept map of chemical bonding: *ionic, covalent, ions, positive ions, negative ions, molecules, polar, and nonpolar*. Define the terms *atom* and *molecule*.
5. **Think Critically** Choose two elements that are likely to form an ionic bond: O, Ne, S, Ca, K. Next, select two elements that would likely form a covalent bond. Explain.

Applying Math

6. **Solve One-Step Equations** Aluminum oxide, Al₂O₃, can be produced during space shuttle launches. Show that the sum of the positive and negative charges in a unit of Al₂O₃ equals zero.

section 2 review

1. In ionic bonds, one atom accepts electrons from another. This happens only among elements having large differences in their attractions for electrons.
2. In ionic bonds, one atom accepts an electron from another atom.
3. Covalent bonding produces molecules.
4. Check students' work.
5. Ionic: Ca–O and K–O, because K and Ca are metals far from O on the periodic table; covalent: S–O because S and O are nonmetals close to each other on the periodic table.
6. The charge on Al is +3 and the charge on O is [2 (+3)] + [3 (–2)] = 0.

Writing Formulas and Naming Compounds

Reading Guide

What You'll Learn

- **Explain** how to determine oxidation numbers.
- **Write** formulas and names for ionic compounds.
- **Write** formulas and names for covalent compounds.

Why It's Important

The name and the formula convey information about the compound.

Review Vocabulary

anion: a negatively charged ion

New Vocabulary

- binary compound
- oxidation number
- polyatomic ion
- hydrate

Binary Ionic Compounds

Does the table in **Figure 19** look like it has anything to do with chemistry? It is an early table of the elements made by alchemists, scientists who tried to make gold from other elements. The alchemists used symbols to write the formulas of substances. The first formulas of compounds that you will write are for binary ionic compounds. A **binary compound** is one that is composed of two elements. Potassium iodide, the salt additive mentioned in Section 2, is a binary ionic compound. Before you can write a formula, you must have all the needed information at your fingertips. What will you need to know?

Oxidation Numbers You need to know which elements are involved and what number of electrons they lose, gain, or share to become stable. Section 1 discussed the relationship between an element's position on the periodic table and the number of electrons it gains or loses. Because all elements in a given group have the same number of electrons in their outer energy levels, they must gain or lose the same number of electrons. Metals always lose electrons and nonmetals always gain electrons when they form ions. The charge on the ion is known as the **oxidation number** of the atom.

For ionic compounds, the oxidation number is the same as the charge on the ion. For example, a sodium ion has a charge of $1+$ and an oxidation number of $1+$. A chloride ion has a charge of $1-$ and an oxidation number of $1-$.

For Best Results, Add Water

Chapter 22

Why are these workers trying to keep the concrete wet rather than letting it dry? Concrete doesn't harden because it dries. It hardens by incorporating water into its molecular structure. If there's not enough water, the concrete won't harden properly, and it won't be very durable.

- How might construction be different in the desert compared to a rainy, temperate region?
- What would happen if a bag of dry concrete got a little damp? What if it got very wet?
- When a new sidewalk is finally dry, where does the water go?

2 Teach

Quick Demo Ion Charge

Materials cellophane tape

Estimated Time 5 minutes

Procedure Binary ionic compounds form when oppositely charged ions attract each other. Demonstrate the basic forces involved by placing two 25-cm pieces of cellophane tape side by side on a plastic surface. Pull both up at the same time. As they are brought close together they will repel. Explain that this happens because both pieces of tape have acquired the same charge. Place one piece of tape on the surface and a second piece directly on top of the first. Pull them off the table and separate them. They now attract each other. Why? They have acquired opposite charges, which causes them to attract each other. **L1 Visual-Spatial**

IDENTIFYING

Misconceptions

Roman Numerals The use of Roman numerals can be confusing. Copper(II) oxide is CuO , with one copper atom for each oxygen atom. The compound copper(I) oxide is written as Cu_2O , with two copper atoms for each oxygen atom. Remind students that the Roman numeral represents the charge on an atom, while Arabic subscript numbers, such as 2 and 3, show the number of atoms of each element.

Caption Answer

Figure 20 The number at the top of each column is the most common oxidation number of elements in that group.

Define oxidation number.

Oxidation Numbers and the Periodic Table The numbers with positive or negative signs in **Figure 20** are the oxidation numbers for the elements in the columns below them. Notice how they fit with the periodic-table groupings.

The elements in **Table 3** can have more than one oxidation number. When naming these compounds, the oxidation number is expressed in the name with a roman numeral. For example, the oxidation number of iron in iron(III) oxide is 3^+ .

Reading Check What is the oxidation number for barium, Ba?

Table 3 Special Ions

Name	Oxidation Number
Copper(I)	1^+
Copper(II)	2^+
Iron(II)	2^+
Iron(III)	3^+
Chromium(II)	2^+
Chromium(III)	3^+
Lead(II)	2^+
Lead(IV)	4^+

Ionic Compounds Are Neutral When writing formulas, it is important to remember that although the individual ions in a compound carry charges, the compound itself is neutral. A formula must have the same number of positive ions and negative ions so the charges balance. For example, sodium chloride is made up of a sodium ion with a 1^+ charge and a chloride ion with a 1^- charge.

However, what if you have a compound such as calcium fluoride? A calcium ion has a charge of 2^+ and a fluoride ion has a charge of 1^- . In this case, you need to have two fluoride ions for every calcium ion for the charges to cancel and the compound to be neutral with the formula CaF_2 .

Some compounds require more thought. Aluminum oxide contains an ion with a 3^+ charge and an ion with a 2^- charge. You must find the least common multiple of 3 and 2 to determine how many of each ion you need. You need two aluminum ions and three oxygen ions to have a 6^+ charge and, a 6^- charge and, therefore, the neutral compound Al_2O_3 .

Science Journal

Oxidation Number Have students use a periodic table to identify the oxidation numbers of the elements in Groups 1, 2, and 13–18. Ask students to make tables containing this information in their Science Journals. **L1 IS Visual-Spatial**

Active Reading

Reflective Journal Have students identify what they learned from activities. Then divide sheets of paper into several columns and record their thoughts under headings such as *What I did*, *What I learned*, *Questions I have*, *Surprises I experienced*, and *Overall response*. Have students write a Reflective Journal for writing formulas.

Writing Formulas After you've learned how to find the oxidation numbers and their least common multiple, you can write formulas for ionic compounds. Write the formula for an ionic compound containing sodium and oxygen by using the following rules in this order.

1. Write the symbol of the element that has the positive oxidation number or charge. Sodium, a Group 1 element, has an oxidation number of 1+.
2. Write the symbol of the element with the negative number. Nonmetals other than hydrogen have negative oxidation numbers. Oxygen has an oxidation number of 2-.
3. To have a neutral compound, the positive charges have to balance the negative charges. It takes two sodium ions to balance the one oxygen ion. Thus, the formula becomes Na_2O .

Jöns Jakob Berzelius

As a Swedish chemist, Berzelius is credited with developing the concepts of ions and ionic compounds. Because of his many interests and discoveries in chemistry, Berzelius, like Antoine Lavoisier, is known as one of the founders of modern chemistry.

Jöns Jakob Berzelius Berzelius, who was trained as a medical doctor, was a professor at Stockholm School of Surgery. He started in the chemical field by writing a chemistry book for his medical students. While doing research for his book, he discovered the law of constant proportion.

Research Have students research which elements that Berzelius discovered. *silicon, selenium, thorium, cerium*

Applying Math Writing Chemical Formulas

DETERMINING A FORMULA What is the formula for lithium nitride?

IDENTIFY known values

Identify the known values:

Symbol and oxidation number of the positive element:

Lithium $\xrightarrow{\text{means}}$ Li^{1+}

Symbol and oxidation number of the negative element:

Nitrogen $\xrightarrow{\text{means}}$ N^{3-}

SOLVE the problem

To have a neutral compound, it takes three Li^{1+} ions to balance the one N^{3-} ion.

$3\text{Li}^{1+} = 1\text{N}^{3-} \xrightarrow{\text{means}} \text{Li}_3\text{N}_1 \text{ or } \text{Li}_3\text{N}$

Reduce the subscripts to the smallest whole numbers that retain the ratios of ions.

CHECK the answer

Does your answer seem reasonable? Check your answer by determining whether your compound is neutral.

Practice Problems

1. What is the formula for lead (IV) phosphide?
2. What is the formula for iron (III) oxide?

For more practice problems go to page 879, and visit Math Practice at fl.gpscience.com.

Applying Math

Math Standards

National: 2, 6, 9

Florida: MA.A.3.4.1

This is what you know: Write the symbol and oxidation number of the positive element: Lead (Pb) = 4+

Write the symbol and oxidation number of the negative element:

Phosphorus (P) = 3-

Least common multiple = 12

This is what you need to do:

Add subscripts so that the sum of the oxidation numbers is zero.

$3\text{Pb} = (3)(4+) = 12+$

$4\text{P} = (4)(3-) = 12-$

Complete the formula.

Answers to Practice Problems

1. Pb_3P_4

2. Fe_2O_3

Activity

Ion Names Give students a list of compound names that consist of the various ions presented in this chapter. Have them write and balance the formula so that the net charge is zero.

Differentiated Instruction

Challenge Have the students inspect the ingredient list on the side of various containers and find five chemical formulas. Have them determine the oxidation numbers of the various elements in each of the five compounds and make a table to exhibit their findings. **L3**

Curriculum Connection

Language Arts The binary ionic compound Fe_3O_4 is the naturally magnetic mineral magnetite. Magnetite was used in the ancient world as a compass; it was called a *lodestone*. Ask students to find out where the name magnetite comes from. Magnetite was named by the ancient Greeks after the place it was originally found, Magnesia in what is now Turkey. **L2**

Linguistic

Activity

Compound Teams Organize the class into two teams. Have team one make a list of the names of compounds and write the names on the board. Team two must then write the correct formula next to each compound. Award one point for each correct answer. Then have team two make a list of compound formulas and write them on the board for team one to name. Alternate between the teams until one reaches a score of 10. **L2** **ELL** **COOP LEARN** **IS**

Answers

1. copper(II) oxide
2. aluminum chloride

Reading Strategy

Metacognitive Strategies

Metacognitive involves self-regulation of thinking and the use of strategies to support comprehension. Model this strategy by reading aloud. Articulate thoughts regarding word meaning, content, and integration of ideas. Show students how to use prior knowledge to aid comprehension.

Table 4 Elements in Binary Compounds

Element	-ide Name
Oxygen	oxide
Phosphorus	phosphide
Nitrogen	nitride
Sulfur	sulfide

Writing Names You can name a binary ionic compound from its formula by using these rules.

1. Write the name of the positive ion.
2. Using **Table 3**, check to see if the positive ion is capable of forming more than one oxidation number. If the ion has only one possible oxidation number, proceed to step 3. If it has more than one, determine the oxidation number of the ion from the formula of the compound. To do this, keep in mind that the overall charge of the compound is zero and the negative ion has only one possible charge. Write the charge of the positive ion using roman numerals in parentheses after the ion's name.
3. Write the root name of the negative ion. The root is the first part of the element's name. For chlorine, the root is *chlor-*.
4. Add the ending *-ide* to the root. **Table 4** lists several elements and their *-ide* counterparts. For example, sulfur in a binary compound becomes sulfide.

Subscripts do not become part of the name for ionic compounds. However, subscripts can be used to help determine the charges of these metals that have more than one positive charge.

Applying Science

Can you name binary ionic compounds?

What would a chemist name the compound CuCl ?

Identifying the Problem

There are four simple steps in naming binary ionic compounds.

1. Write the name of the positive ion in the compound. In CuCl , the name of the positive ion is copper.
2. Check **Table 3** to determine whether copper is one of the elements that can have more than one oxidation number. Looking at **Table 3**, you can see that copper can have a $1+$ or a $2+$ oxidation number. You need to determine which to use. Looking at the compound, you see that there is one copper atom and one chlorine atom. You know that

the overall charge of the compound is zero and that chlorine only forms a $1-$ ion. For the charge of the compound to be zero, the charge of the copper ion must be $1+$. Write this charge using roman numerals in parentheses after the element's name, copper(I).

3. Write the root name of the negative ion. The negative ion is chlorine and its root is *chlor-*.
4. Add the ending *-ide* to the root, *chloride*.
5. The full name of the compound CuCl is copper(I) chloride.

Solving the Problem

1. What is the name of CuO ?
2. What is the name of AlCl_3 ?

Teacher FYI

Hydrogen's Assignment Hydrogen is nearly always found with a $+1$ charge. However, when hydrogen combines with active metals such as those found in Groups 1 and 2, it is assigned a -1 charge. This assignment is

made because of the ease with which those metals lose electrons to become $+1$ ions. Examples include NaH and MgH_2 . These compounds are called sodium hydride and magnesium hydride.

Compounds with Polyatomic Ions

Not all ionic compounds are binary. Baking soda—used in cooking, as a medicine, and for brushing your teeth—has the formula NaHCO_3 . This is an example of an ionic compound that is not binary. Some ionic compounds are composed of more than two elements. They contain polyatomic ions. The prefix *poly-* means “many,” so the term *polyatomic* means “having many atoms.” A **polyatomic ion** is a positively or negatively charged, covalently bonded group of atoms. Thus, the polyatomic ions as a whole contain two or more elements. The polyatomic ion in baking soda is the bicarbonate or hydrogen carbonate ion, HCO_3^- .

Writing Names Several polyatomic ions are listed in **Table 5**. To name a compound that contains one of these ions, first write the name of the positive ion. Use **Table 5** to find the name of a polyatomic ion. Then write the name of the negative ion. For example, K_2SO_4 is potassium sulfate. What is the name of $\text{Sr}(\text{OH})_2$? Begin by writing the name of the positive ion, strontium. Then find the name of the polyatomic ion, OH^- , which is hydroxide. Thus, the name is strontium hydroxide.

Writing Formulas To write formulas for these compounds, follow the rules for binary compounds, with one addition. When more than one polyatomic ion is needed, write parentheses around the polyatomic ion before adding the subscript. How would you write the formula of barium chlorate?

First, identify the symbol of the positive ion. Barium has the symbol Ba and forms a $2+$ ion, Ba^{2+} . Next, identify the negative chlorate ion. **Table 5** shows that it is ClO_3^- . Finally, you need to balance the charges of the ions to make the compound neutral. It will take two chlorate ions with a $1-$ charge to balance the $2+$ charge of the barium ion. Because the chlorate ion is polyatomic, you use parentheses before adding the subscript. The formula is $\text{Ba}(\text{ClO}_3)_2$. Another example of naming complex compounds is shown in **Figure 21**.

Table 5 Polyatomic Ions

Charge	Name	Formula
$1+$	ammonium	NH_4^+
$1-$	acetate	$\text{C}_2\text{H}_3\text{O}_2^-$
	chlorate	ClO_3^-
	hydroxide	OH^-
	nitrate	NO_3^-
$2-$	carbonate	CO_3^{2-}
	sulfate	SO_4^{2-}
$3-$	phosphate	PO_4^{3-}

Figure 21 Naming Complex Compounds

How would a scientist write the chemical formula for ammonium phosphate?

To write the formula, answer the following questions:

- What is the positive ion and its charge?
The positive ion is NH_4^{1+} and its charge is $1+$.
- What is the negative ion and its charge?
The negative ion is PO_4^{3-} and its charge is $3-$.
- Balance the charges to make the compound neutral.
 - three NH_4^{1+} ions ($+3$) balance one PO_4^{3-} ($3-$)
 - The charge of one ion (without the sign) becomes the subscript of the other. Add parentheses for subscripts greater than 1.
 NH_4^{1+} PO_4^{3-} gives $(\text{NH}_4)_3\text{PO}_4$

The chemical formula for ammonium phosphate is $(\text{NH}_4)_3\text{PO}_4$.

Discussion

Polyatomic Ions Provide practice using polyatomic ions by having students name each of the following compounds and determine the number of atoms of the underlined element in each: $\text{Na}_3\text{PO_4}$, 4 oxygen atoms, sodium phosphate; $\text{Al}_2(\text{CO)_3)_3$, 3 carbon atoms, aluminum carbonate; $\text{Ca}(\text{C}_2\text{H}_3\text{O}_2)_2$, 6 atoms of hydrogen, calcium acetate **L2** **IS** Logical-Mathematical

Fun Fact

Anhydrous compounds such as CaCl_2 are sometimes sold as products to reduce humidity. Anhydrous calcium chloride absorbs moisture to become a hydrate in a moist basement.

Cultural Diversity

Silicon Dioxide The binary covalent compound silicon dioxide, SiO_2 , also known as quartz or rock crystal, has been revered in many cultures since ancient times. Have students report on some of the legends associated with SiO_2 . Japanese, ancient Greek, Cherokee Indian, Burmese, Irish, and Scottish are some of the cultures that have legends surrounding SiO_2 . **P**

Differentiated Instruction

Challenge Have students find the formulas, names, or charges of the following polyatomic ions: nitrite, NO_2^- ; sulfite, SO_3^{2-} ; MnO_4^- , permanganate; ClO_2^- , chlorite. **L3** **IS** Logical-Mathematical

Use Science Words

Word Usage Have students use the word *hydrate* in a sentence in a way that describes its meaning. Possible answer: A hydrate forms when water molecules become attached to the ions of a compound. **L1** **AS** Linguistic

Video Lab available.

Purpose Students will create their own hydrates.

Materials plaster of paris, water, small bowl, rubber hammer, hair dryer for each student

Teaching Strategy Ask students to show their final products to the class.

Analysis

1. The plaster should not crack when tapped before it is heated, but it becomes brittle and cracks easily after being heated.
2. Steam will rise from the plaster, and it will easily crumble and become powder. The heat removes water molecules from the hydrated gypsum causing the plaster to lose its strength.

Assessment

Performance Ask students to experiment with different proportions of water and plaster of paris to create hydrates with different heat and stress-resistant properties. Use **Performance Assessment in the Science Classroom**, p. 89.

Caption Answer

Figure 22 CaSO_4

Making a Hydrate

Procedure

1. Mix 150 g of plaster of paris with 75 mL of water in a small bowl.
2. Let the plaster dry overnight and then take the hardened plaster out of the bowl.
3. Lightly tap the plaster with a rubber hammer.
4. Heat the plaster with a hair dryer on the hottest setting and observe.
5. Place a towel over the sample, then lightly tap the plaster with the hammer after heating it.

Analysis

1. What happened to the plaster when you tapped it before and after heating it?
2. What did you observe happening to the plaster as you heated it? Explain.

Compounds with Added Water

Some ionic compounds have water molecules as part of their structure. These compounds are called hydrates. A **hydrate** is a compound that has water chemically attached to its ions and written into its chemical formula.

Common Hydrates The term *hydrate* comes from a word that means “water.” When a solution of cobalt chloride evaporates, pink crystals that contain six water molecules for each unit of cobalt chloride are formed. The formula for this compound is $\text{CoCl}_2 \cdot 6\text{H}_2\text{O}$ and is called cobalt chloride hexahydrate.

You can remove water from these crystals by heating them. The resulting blue compound is called anhydrous, which means “without water.” When anhydrous (blue) CoCl_2 is exposed to water, even from the air, it will revert back to its hydrated state.

The plaster of paris shown in **Figure 22** also forms a hydrate when water is added. It becomes calcium sulfate dihydrate, which is also known as gypsum. The water that was added to the powder became a part of the compound.

To write the formula for a hydrate, write the formula for the compound and then place a dot followed by the number of water molecules. The dot in the formula represents a ratio of a compound to water molecules. For example, calcium sulfate dihydrate, $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$, is the formula for the hydrate of calcium sulfate that contains two molecules of water.

Naming Binary Covalent Compounds

Covalent compounds are those formed between elements that are nonmetals. Some pairs of nonmetals can form more than one compound with each other. For example, nitrogen and oxygen can form N_2O , NO , NO_2 and N_2O_5 . In the system you have learned so far, each of these compounds would be called nitrogen oxide. You would not know from that name what the composition of the compound is.

Figure 22 The presence of water changes this powder into a material that can be used to create art.

Identify the formula for this powder prior to the addition of water.

708 CHAPTER 22 Chemical Bonds

LAB DEMONSTRATION

Purpose to observe the difference between a hydrated and a dehydrated compound

Materials copper(II) sulfate pentahydrate, test tube, Bunsen burner, water, dropper

Procedure Place a small amount of copper(II) sulfate pentahydrate in the tube and heat it in a flame. Have students

observe the change. Let tube cool, then add a few drops of water.

Expected Outcome When heated, the deep blue copper(II) sulfate pentahydrate gradually changes into the white powder of the anhydrous compound. When water is added, the blue hydrate is restored.

Assessment

Write the formula for copper(II) sulfate pentahydrate. $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$ Was this a chemical change or a physical change? **A chemical change; it changed the identity of the material.**

Using Prefixes Scientists use the Greek prefixes in **Table 6** to indicate how many atoms of each element are in a binary covalent compound. The nitrogen and oxygen compounds N_2O , NO , NO_2 , and N_2O_5 would be named dinitrogen oxide, nitrogen oxide, nitrogen dioxide, and dinitrogen pentoxide. Notice that the last vowel of the prefix is dropped when the second element begins with a vowel, as in pentoxide. Often, the prefix *mono-* is omitted, although it is used for emphasis in some cases. Carbon monoxide is one example.

Reading Check What prefix would be used for seven atoms of one element in a covalent compound?

These same prefixes are used when naming the hydrates previously discussed. The main ionic compound is named the regular way, but the number of water molecules in the hydrate is indicated by the Greek prefix.

You have learned how to write formulas of binary ionic compounds and of compounds containing polyatomic ions. Using oxidation numbers to write formulas, you can predict the ratio in which atoms of elements might combine to form compounds. You also have seen how hydrates have water molecules as part of their structures and formulas. Finally, you have learned how to use prefixes in naming binary covalent compounds. As you continue to study, you will see many uses of formulas.

Table 6 Prefixes for Covalent Compounds

Number of Atoms	Prefix
1	<i>mono-</i>
2	<i>di-</i>
3	<i>tri-</i>
4	<i>tetra-</i>
5	<i>penta-</i>
6	<i>hexa-</i>
7	<i>hepta-</i>
8	<i>octa-</i>

Reading Check

Answer *hepta-*

Post Reading

Science Journal Have students respond to the following prompt: Explain how binary compounds and compounds with complex ions are named. Include information regarding the formation of these compounds and the chemical formulas used to represent them. Have students read and discuss their responses with a partner.

3 Assess

DAILY INTERVENTION

Check for Understanding

Logical-Mathematical Have students read the labels of various products and find five compounds that have names with the numeric prefixes. Have them write out the formula for each of these compounds.

Reteach

Prefix Ask students why calcium chloride (CaCl_2) is named without using the prefix system shown in **Table 5**, while carbon tetrachloride (CCl_4) does use a prefix to designate the number of chlorine atoms. The prefix system is used for covalent compounds between nonmetals. CaCl_2 is ionic.

section 3 review

Summary

Binary Ionic Compounds

- A binary compound is one composed of two elements.
- The oxidation number tells how many electrons an atom has gained, lost, or shared to become stable.
- The net charge of a compound is zero.

Compounds with Complex Ions

- A polyatomic ion is a positively or negatively charged, covalently bonded group of atoms.
- A hydrate is a compound that has water chemically attached to its ions.
- Greek prefixes are used to indicate how many atoms of each element are in a binary covalent compound.

Self Check

1. **Use Formulas** Write formulas for the following compounds: potassium iodide, magnesium hydroxide, aluminum sulfate, and chlorine heptoxide.
2. **Use Formulas** Write the names of these compounds: KCl , Cr_2O_3 , $\text{Ba}(\text{ClO}_3)_2$, NH_4Cl , and PCl_3 .
3. **Name** $\text{Mg}_3(\text{PO}_4)_2 \cdot 4\text{H}_2\text{O}$ and write the formula for calcium nitrate trihydrate.
4. **Think Critically** Explain why sodium and potassium will or will not react to form a bond with each other.

Applying Math

5. **Solve One-Step Equations** The overall charge on the polyatomic sulfate ion, found in some acids, is 2^- . Its formula is SO_4^{2-} . If the oxygen ion has a 2^- oxidation number, determine the oxidation number of sulfur in this polyatomic ion.

SECTION 3 Writing Formulas and Naming Compounds 709

section 3 review

1. KI ; $\text{Mg}(\text{OH})_2$; $\text{Al}_2(\text{SO}_4)_3$; Cl_2O_7
2. potassium chloride; chromium(III) oxide; barium chlorate; ammonium chloride; phosphorus trichloride
3. magnesium phosphate tetrahydrate; $\text{Ca}(\text{NO}_3)_2 \cdot 3\text{H}_2\text{O}$
4. Sodium and potassium will bond with atoms that are able to easily accept electrons. They would have a difficult time bonding with each other because both tend to lose electrons.
5. Oxygen contributes $4 \times -2 = -8$. The total charge is -2 , so sulfur must contribute $+6$.

MA.A.3.4.1

Assessment

Performance The common name for $\text{Na}_2\text{B}_4\text{O}_5(\text{OH})_4 \cdot 8\text{H}_2\text{O}$ is borax. It is used as an important source of boron and can also be used as a washing powder. Ask students to determine the number of oxygen atoms in the molecule. Use **PASC**, p.101.

Real-World Problem

Purpose Students will compare and contrast chemical formulas by making models of chemical bonding using outer energy levels. **L3 K Kinesthetic**

Process Skills classify, communicate, compare and contrast, draw, label, infer, interpret scientific illustrations, organize data, think critically

Time Required class period

Safety Precautions Do not use candy in place of beans. You should not encourage eating in the lab.

Form a Hypothesis

Possible Hypothesis Students may hypothesize that ionic bonding occurs with the transfer of electrons to form ions and that covalent bonding occurs when electrons are shared between atoms.

Test Your Hypothesis

Possible Procedures Give students three to nine beans. This will allow them to model lithium to fluorine. Encourage students to work with other students to model ionic bonding (transfer of electrons) and covalent bonding (sharing of electrons).

Teaching Strategies

- Using the egg carton, block off two of the egg spaces and review with students the capacity of first and second energy levels.

Modeling Chemical Bonding**Real-World Problem**

Chemical bonding is one of the most important concepts in chemistry. Bonding is what makes different compounds. Even though atoms have a nucleus containing protons and neutrons, the part of the atom that is most important to chemists is outside the nucleus. How are electrons involved in chemical bonding?

Make a Model

- Obtain a modified egg carton and beans from your teacher. The egg carton represents the first and second energy levels of an atom. The beans represent electrons.
- Decide** which elements you can model by the number of beans you have. Consider how the periodic table can be used to determine the number of outer electrons in an element.
- Model** all the elements that you can create using the modified egg carton and beans.
- Draw** the models of elements that you created in your Science Journal.
- Determine** if the elements form ionic or covalent bonding. Record your conclusions in your Science Journal.

Goals

- Infer** chemical formulas by making models of outer electron levels.
- Compare and contrast** models of ionic and covalent bonding.
- Draw and label** diagrams to illustrate chemical bonding.

Possible Materials

modified egg carton
beans

*pennies

*buttons

*Alternate materials

Safety Precautions

Complete a safety worksheet before you begin.

Using Scientific Methods

Test Your Model

1. Look for element combinations that could represent chemical formulas for compounds and molecules. Some formulas may require more than one atom to form some types of elements and compounds.
2. Work with other students to make models of compounds and molecules produced by chemical bonding.
3. **Draw** the models of the compounds and molecules you made in your Science Journal. Record the type of bonding used to make the compounds and molecules.

Analyze Your Data

1. **Explain** how you can use the periodic table to identify the element that represents your model.
2. **Explain** whether elements in the metal groups on the periodic table have more or fewer electrons in their outer energy levels than the nonmetals.
3. The combinations of elements could represent chemical formulas. Explain why some formulas require more than one atom of an element.

Conclude and Apply

1. **Describe** why your model could be used to show examples of both ionic and covalent bonding.
2. **Predict** what element your model would be if you received ten beans. Explain your reasoning.

Communicating Your Data

Compare your conclusions with other students' conclusions. What elements did their models represent? Explain how their elements differed in ability to form ionic and covalent bonds.

Expected Outcome Monitor students so they discover simple matchups such as LiF and progress to compounds such as BeF_2 , Li_2O , BeO , and Be_3N_2 . Remind students that elements can achieve stability by losing, gaining, or sharing electrons.

Analyze Your Data

1. Using the periodic table, three beans would represent lithium, four beans beryllium, and so forth up to nine beans representing fluorine.
2. In general, metals have fewer electrons than nonmetals.
3. Formulas such as BeF_2 show more fluorine is needed to balance the charge in this compound.

Conclude and Apply

1. Elements have the ability to lose, gain, or share electrons.
2. This would represent neon, a noble gas that has a stable arrangement of eight outer level electrons.

LAB 711

Assessment

Oral Have students explain compounds or molecules using their model that were not done during the experiment. Use **Performance Assessment in the Science Classroom**, p. 143.

Communicating Your Data

Share drawings of models with other students.

Content Background

Glue has been around for a long time. Egyptian carvings dating back 3,300 years show figures gluing thin pieces of veneer to sycamore planks. Throughout history, most glues came from a variety of natural sources, including beeswax, flour paste, egg whites, cheese, and extracts from animal horns and fish. Only in the recent century did synthetic glues become more prominent. Glues work because they are able to seep into the crevices of a surface and form chemical welds to the molecules on that surface. Strong polymer chains give glues their strength and flexibility.

Activity

Glue Experiment Let small groups of students experiment with their own glue. Give each group 15 mL of unflavored gelatin in a small beaker. Pour 25 mL of boiling water into the gelatin

WARNING: *Be careful with the hot water.* Have students stir the mixture until the gelatin dissolves. Let them use paintbrushes to apply the glue to various types of materials such as paper, wood, and plastic to see which kinds of materials the glue will bond together.

Analyze the Event

Explain to students that Louis Pasteur was a French scientist who discovered, among other things, the rabies vaccine and the pasteurization process for milk. Write the following quote of Pasteur's on the board: "In the field of observation, chance favors the prepared mind." Ask students to brainstorm what they think the quote means and how it applies to this feature. **Possible answers:** The first group of researchers didn't realize the possibilities of the discovery, but the later group did, so the later group had "prepared minds."

A Sticky Subject

In 1942, a research team was working on creating a new kind of glass. The group was working with some cyanoacrylate monomers (si uh noh A kruh layt • MAH nuh muhrz) that showed promise, but a problem kept coming up. Everything the monomers touched stuck to everything else!

Cyanoacrylate is the chemical name for instant, supertype glues. The researchers were so focused on finding a different type of glass that at the time, none of them recognized that they were working with an important new adhesive.

In 1952, a member of the research team, working on new materials for jet plane canopies, made a similar complaint. The ethyl cyanoacrylate the team was working with again made everything stick together. This time, the insight stuck to the scientists like, well, like GLUE! "I began gluing everything I could lay my hands on—glass plates, rubber stoppers,

metal spatulas, wood, paper, plastic. Everything stuck to everything, almost instantly, and with bonds I could not break apart," recalls the head of the research group.

Stick to It

Most adhesives, commonly called glues, are long chains of bonded molecules called polymers. Cyanoacrylate, however, exists as monomers—single molecules with double bonds. And it stays that way until it hits anything with moisture in it, such as air. Yes, even the small amount of moisture in air and on the surfaces of most materials is enough to dissolve the double bonds in the monomers of cyanoacrylate, making them join together in long chains. The chains bond to surfaces as they polymerize.

The discovery of cyanoacrylates had an immediate impact on the automobile and airplane industries. And it soon "held" a spot in almost every household toolbox. Since the 1990s, cyanoacrylate glues have also found a place in doctors' offices. A doctor can apply a thin layer of instant glue instead of putting stitches in a cut. This specially made medical glue was approved by the U.S. Food and Drug Administration in 1998.

Take Note Visit a store and make a table of different kinds of glues. List their common names, their chemical names, what they are made of, how long it takes them to set, and the types of surfaces for which they are recommended. Note any safety precautions.

For more information, visit fl.gpscience.com

Take Note Tell students to pay careful attention to the recommended uses for each type of glue. Ask students why one glue cannot meet all people's needs. (Possible answers: Some glues can be toxic and so wouldn't be useful for gluing drinking cups, as shown in the feature. Some glues might react chemically with paper or wood. Some glues aren't waterproof.)

Resources for Teachers and Students

"Adhesion," Encyclopedia Britannica

Reviewing Main Ideas

Section 1 Stability in Bonding

1. The properties of compounds are generally different from the properties of the elements they contain.
2. A chemical formula for a compound indicates the composition of a unit of the compound. This model of a water molecule shows the shape of the molecule and the relative sizes of the atoms.
3. Chemical bonding occurs because atoms of most elements become more stable by gaining, losing, or sharing electrons to obtain stable outer energy levels.

Section 2 Types of Bonds

1. Covalent bonds are formed by the sharing of electrons. Ionic bonds between atoms are formed by the attraction between ions. Below is an example of an ionically bonded compound.

2. Ionic bonding occurs between charged particles called ions and produces ionic compounds. Covalent bonding produces units called molecules and occurs between nonmetallic elements.

3. The unequal sharing of electrons produces compounds that contain polar bonds, and the equal sharing of electrons produces nonpolar compounds.

Section 3 Writing Formulas and Naming Compounds

1. An oxidation number indicates how many electrons an atom has gained, lost, or shared when bonding with other atoms.
2. In the formula of an ionic compound, the element or ion with the positive oxidation number is written first, followed by the one with the negative oxidation number.
3. The name of a binary compound is derived from the names of the two elements that compose the compound. Salt is an example of a binary compound, sodium chloride.

4. A hydrate is a compound that has water chemically attached to its ions and written into its formula.
5. Greek prefixes are used in the names of covalent compounds. These indicate the number of each atom present.

Assessment

Chemical Bonds

Directions: Carefully review the tables and answer the following questions.

Group A		Group B	
Water	H ₂ O	Epsom salts	Mg(OH) ₂
Carbon dioxide	CO ₂	Sugar	C ₁₂ H ₂₂ O ₁₁
Ammonia	NH ₃	Lye	NaOH
Salt	NaCl	Baking soda	NaHCO ₃
Methane	CH ₄	Vinegar	C ₂ H ₄ O ₂

1. The compounds in Group A are different from the compounds in Group B because only the compounds in Group A _____.
 A are gases at room temperature
 B are used in preparing food
 C contain a metal and a nonmetal
 D contain only two different elements
2. According to the chemical formula for lye, all of the following elements are found in a lye molecule EXCEPT _____.
 F hydrogen
 G nitrogen
 H oxygen
 I sodium
3. According to the information contained in the tables, which compound has a total number of atoms greater than 10?
 A Baking soda
 B Methane
 C Sugar
 D Vinegar
4. According to the tables, which compound has the LEAST number of total atoms?
 F Ammonia
 G Carbon dioxide
 H Salt
 I Water

FCAT Vocabulary

Match each phrase with the correct vocabulary word or phrase.

1. a charged group of atoms
2. a compound composed of two elements
3. a molecule with partially charged areas
4. a positively or negatively charged particle
5. a chemical bond between oppositely charged ions
6. a bond formed from shared electrons
7. a crystalline substance that contains water
8. a particle made of covalently bonded atoms
9. shows an element's combining ability
10. tells which elements are in a compound and their ratios.

Checking Concepts

Choose the word or phrase that best answers the question.

11. Which elements are least likely to react with other elements?
A) metals C) nonmetals
B) noble gases D) transition elements
12. What is the name of CuO ?
A) copper oxide
B) copper(I) oxide
C) copper(II) oxide
D) copper(III) oxide

13. Which formula represents a nonpolar molecule?
A) N_2 C) $NaCl$
B) H_2O D) HCl
14. How many electrons are in the outer energy levels of Group 17 elements?
A) 1 C) 7
B) 2 D) 17
15. Which is a binary ionic compound?
A) O_2 C) H_2SO_4
B) NaF D) $Cu(NO_3)_2$
16. Which is an anhydrous compound?
A) H_2O C) $CuSO_4 \cdot 5H_2O$
B) $CaSO_4$ D) $CaSO_4 \cdot 2H_2O$
17. Which atom has gained an electron?
A) negative ion
B) positive ion
C) polar molecule
D) nonpolar molecule
18. Which is a covalent compound?
A) sodium chloride
B) calcium fluoride
C) calcium chloride
D) sulfur dioxide

Interpreting Graphics

19. Copy and complete the concept map.

Use the ExamView® Pro Testmaker CD-ROM to:

- create multiple versions of tests

20. **Identify** and write the name and formula for the compound illustrated to the right.

Use the table below to answer question 21.

Which compounds exist?

Formula	Possible Compounds
SF ₆	AlF ₆ or TeF ₆
K ₂ SO ₄	Na ₂ SO ₄ or Ba ₂ SO ₄
CO ₂	CCl ₂ or CS ₂
CaCO ₃	OCO ₃ or BaCO ₃

21. **Predict** Elements from one family (vertical column) of the periodic table generally combine with elements from another family and polyatomic ions in the same ratio. For example, one calcium atom combines with two chlorine atoms to give CaCl₂ (calcium chloride), as it does with two fluorine atoms to give CaF₂ (calcium fluoride). Using the periodic table as a guide, predict which of the two compounds on the right side of the table above is more likely to exist based upon the formula on the left side.

Thinking Critically

22. **Draw** Anhydrous magnesium chloride is used to make wood fireproof. Draw a dot diagram of magnesium chloride.
23. **Use Formulas** Artificial diamonds are made using thallium carbonate. If thallium has an oxidation number of 1+, what is the formula for the compound?
24. **Compare and contrast** polar and nonpolar molecules.

25. **Write** Baking soda, which is sodium hydrogen carbonate, and vinegar, which contains hydrogen acetate, can be used as household cleaners. Write the chemical formulas for these two compounds.

26. **Draw Conclusions** Ammonia gas and water react to form household ammonia, which contains NH₄⁺ and OH⁻ ions. The formula for water is H₂O. What is the formula for ammonia gas?

27. **Draw Conclusions** The name of a compound called copper(II) sulfate is written on a bottle. What is the charge of the copper ion? What is the charge of the sulfate ion?

28. **Explain** what electric forces between oppositely charged electrons and protons have to do with chemical reactions.

29. **Name Compounds** Write the chemical name for the following compounds.

- A) Fe₂S₃ C) Ca(PO₄)₂
B) Cu(ClO₃)₂ D) (NH₄)₂SO₄

30. **Model** One common form of phosphorus, white phosphorus, has the formula P₄ and is formed by four covalently bonded phosphorus atoms. Make a model of this molecule, showing that all four atoms are now chemically stable.

31. **Determine** the chemical formulas for the following compounds.

- A) potassium chloride
B) calcium carbonate
C) copper sulfate
D) sodium oxide

Applying Math

32. **Use Numbers** What is the oxidation number of Fe in the compound Fe₂S₃?

- A) 1⁺ C) 3⁺
B) 2⁺ D) 4⁺

Thinking Critically

24. A polar molecule has opposite charges (positive and negative) on each end because of an unequal sharing of electrons. A nonpolar molecule does not have oppositely charged ends because the electrons involved are shared equally.

28. In order to form an ionic charge, the quantity of electrons and protons are unequal. If one element loses electrons, another must gain in order to keep the neutral charge of the compound

29. a. iron sulfide

- b. copper (II) chlorate

- c. calcium phosphate

- d. ammonium sulfate

Use PASC, p. 123

31. a. KCl

- b. CaCO₃

- c. CuSO₄

- d. Na₂O

SAMPLE

Multiple Choice

1. D 4. B 7. B
2. A 5. A
3. A 6. C

Gridded Response

8. 18
9. 18

Short Response

10. Nitrogen and fluorine have oxidation numbers of 23 and 21, respectively. Nitrogen must gain three electrons to fill its outer energy level, while fluorine must gain one.
11. NaCl is an ionic bond. In an ionic bond, a transfer of electrons takes place. Because you have a 1 and a 2 you get a zero net charge. Na 1 1 Cl 2, which gives you a zero net charge.

Record your answers on the answer sheet provided by your teacher or on a sheet of paper. The assessed Florida Benchmark appears above the question.

Multiple Choice

SCA.2.4.2

1. Which statement about this molecule is TRUE?
- A. This is a nonpolar molecule.
B. The electrons are shared equally in the bonds of this molecule.
C. This molecule does not have oppositely charged ends.
D. This is a polar molecule.

Use the figure below to answer question 2.

SCA.1.4.5

2. What type of bond holds the atoms of this molecule together?
- A. covalent
B. ionic
C. triple
D. double

SCA.2.4.5

3. What do the Group 7A elements become when they react with Group 1A elements?
- A. negative ions
B. neutral
C. positive ions
D. polyatomic ions

4. What is the name of $\text{KC}_2\text{H}_3\text{O}_2$?
- A. potassium carbide
B. potassium acetate
C. potassium hydroxide
D. potassium oxide

5. What is the chemical formula for lead(II) oxide?
- A. PbO
B. Pb_2O
C. PbO_2
D. Pb_2O_2

Use the illustration below to answer question 6.

P	S	Cl	Ar

SCA.1.4.5

6. How many electrons are required to complete the outer energy level of a phosphorous atom?
- A. one
B. two
C. three
D. four

Test-Taking Tip

Comprehension Be sure you understand the question before you read the answer choices. Make special note of words like NOT or EXCEPT. Read and consider all the answer choices before you mark your answer sheet.

716 STANDARDIZED TEST PRACTICE

Extended Response

12. HCl is an example of covalent bonding of unequal sharing. Chlorine atoms have a stronger attraction for electrons than hydrogen does. Therefore, the electrons shared in hydrogen chloride will spend more time near the chlorine atom than the hydrogen atom. The

example of a tug-of-war with the knot being the electron shows how the bonding happens. Therefore the electron goes more with the chlorine which is bigger. Ionic bonding is an equal sharing of electrons so that they equal 0. Potassium is a 11 and chlorine

is a 21 which when you put 11 1 21 5 0.

13. This is a covalent bond, formed from sharing of electrons. It is a triple bond, as three pairs of electrons are shared.
14. $\text{H}:\text{H}:\text{O}::\text{O}::\text{F}:\text{F}:$
 $\text{Cl}:\text{Cl}:\text{Br}:\text{Br}:\text{I}:\text{I}:$

7. Which element is **NOT** part of the compound NH_4NO_3 ?

- A. nitrogen
- B. nickel
- C. oxygen
- D. hydrogen

Gridded Response

SCA241

8. When an atom is chemically stable, how many electrons are in its outer energy level?

SCA241

9. How many electrons are there in an argon atom?

Short Response

Use the illustration below to answer question 10.

Oxidation Numbers of Some Period 2 Elements

10. Compare the oxidation numbers of nitrogen and fluorine. Why do they differ?

SCA145

11. The bonding of atoms and molecules is the result of oppositely charged electrons and protons being held together by electric forces within the atoms. Using this information, explain the bonding of NaCl .

Extended Response

SCA145

12. KCl is an example of ionic bonding. HCl is an example of covalent bonding. Describe the difference in the bonds in terms of electrons and outer energy levels.

Use the illustration below to answer question 13.

SCA145

13. Describe the bond holding the nitrogen atoms together in this molecule.

14. Nitrogen occurs naturally as a diatomic molecule because N_2 molecules are more stable than nitrogen atoms. H_2 , O_2 , F_2 , Cl_2 , Br_2 , and I_2 are other diatomic molecules. Draw dot diagrams for three of these molecules.

SCA245

15. Explain why elements in Groups 4A, which have four electrons in their outer energy levels, are unlikely to lose all of the electrons in their outer energy levels.

16. What factors affect how strongly an atom is attracted to its electrons?

17. Create a chart that compares the properties of polar and nonpolar molecules. Your chart should include several examples of each type of molecule.

18. What is the difference between nitrogen oxide and dinitrogen pentoxide? Why are prefixes used to name these compounds?

18. Nitrogen oxide is NO , while dinitrogen pentoxide is N_2O_5 . Prefixes are used to identify the composition of compounds which are made of elements that can form more than one compound with each other.

Rubrics

For more help evaluating Short- and Extended-Response questions, see the rubrics on p. 10T.

15. These elements have four outer shell electrons. It would take a lot of energy to lose four electrons, because each time an electron was lost, the other electrons would be held even more tightly by the nucleus.

16. The size of the atom, the size of the positive charge in the nucleus, and the total number of electrons an atom has all affect the strength of the attraction between an atom and its electrons.

17.

Polar Molecules	Nonpolar Molecules
Have covalent bonds	Have covalent bonds
Electrons are held more closely by one atom of the molecule	Electrons are shared equally
Have slightly positive and slightly negative ends	Do not have oppositely charged ends
Examples: NH_3 , H_2O	Examples: CCl_4 , CH_4

Section Focus

Section Focus Transparency **A Changing World** **Chapter 23**

This family is not only having fun, they're doing chemistry! Toasting marshmallows, burning wood, and getting energy from food all involve changes in substances.

- Describe what you see in this campfire scene. How do some of the things you named look different than they did before the fire was lit?
- How will the marshmallows continue to change if kept in the fire?

L2

Section Focus Transparency **A Balanced Viewpoint** **Chapter 23**

Balance scales have been used for a very long time to compare the weight of different objects. Usually, an unknown weight is put on one pan and known weights are put in the other until the two pans are in balance. In chemical equations, balance is in a similar fashion.

- How is the arrow on a chemical equation like the fulcrum of a balance?
- If you could put all the reactants of a chemical reaction in one pan of a balance and all the products in the other pan, would the two pans be even? Explain.

L2

Section Focus Transparency **Free the Nitrogen!** **Chapter 23**

Nitrogen is the most abundant gas in the atmosphere. However, in the atmosphere, nitrogen is held in molecules by very strong triple bonds. In order to be used by its neighbors, these triple bonds need to be broken. Lightning can supply energy that breaks nitrogen atoms to form as it compounds.

- Do the nitrogen atoms freed by lightning undergo a chemical or physical change?
- Describe what happens to the atoms in the reaction $N_2 + O_2 \rightarrow 2NO$.

L2

Section Focus Transparency **Makes a Great Highlight, Too** **Chapter 23**

The animal you see below is a comb jelly. Most comb jellies are capable of giving off light.

- What type of reaction do you think allows the comb jelly to give off light? Why?
- Why is it important that the comb jelly generates light without heat?

L2

This is a representation of key blackline masters available in the Teacher Classroom Resources. See Resource Manager boxes within the chapter for additional information.

Key to Teaching Strategies

The following designations will help you decide which activities are appropriate for your students.

- L1** Level 1 activities should be appropriate for students with learning difficulties.
- L2** Level 2 activities should be within the ability range of all students.
- L3** Level 3 activities are designed for above-average students.
- ELL** ELL activities should be within the ability range of English Language Learners.
- COOP LEARN** Cooperative Learning activities are designed for small group work.
- LS** Multiple Learning Styles logos, as described on page 12T, are used throughout to indicate strategies that address different learning styles.
- P** These strategies represent student products that can be placed into a best-work portfolio.
- PBL** Problem-Based Learning activities apply real-world situations to learning.

Assessment

Assessment Transparency **Chemical Reactions** **Chapter 23**

Directions: Carefully review the diagrams and answer the following questions.

From the results of the experiment above, it is reasonable to assume that the production of ethene:

- A has no effect on the rotting of a peach in its immediate area.
- B slows the rotting of a peach in its immediate area.
- C quickens the rotting of a peach in its immediate area.
- D slows the rotting process in the peach producing the gas.

According to the information in the diagram, we can conclude that ethene consists of:

- I hydrogen and helium
- II carbon and oxygen
- III carbon and hydrogen
- IV calcium and carbon

George wanted to use the peaches that he picked from the tree in his backyard to bake a pie. However, some were not quite ripe. George could best speed the ripening process by placing the peaches:

- A in the refrigerator
- B inside an enclosed space
- C outside by the tree
- D near a breezy window

Science Content Background

Chemical Changes Conservation of Mass

For his work on conservation of mass, many consider eighteenth-century French scientist Antoine-Laurent Lavoisier to be the founder of modern chemistry. Lavoisier's work, done during the late 1700s, included some of the first quantitative chemical experiments ever performed. He showed that the quantity of matter is the same at the end of a chemical reaction as it is at the beginning of the reaction.

Teacher to Teacher

Jaime A. Sullivan,
South Caldwell High School
Hudson, NC

"One way to get a reaction out of the kids is to demonstrate with fire. In this case, I use a mixture of baking soda and vinegar to produce carbon dioxide, then I douse a lit candle in the CO_2 . Now that they're wondering how the flame was put out, I explain that a chemical reaction took place and I show them the chemical formulas for vinegar (aqueous acetic acid, $\text{C}_2\text{H}_4\text{O}_2(\text{aq})$) and baking soda (sodium hydrogen carbonate, NaHCO_3). I let them determine on their own (and they eventually will) that what is actually produced is $\text{CO}_2(\text{g})$."

Jaime A. Sullivan

While most of Lavoisier's experiments centered on combustion, he also investigated the composition of water. In fact, he named the two components of water—hydrogen and oxygen. With the help of other scientists, he devised a chemical naming system that served as the basis of the modern system.

Lavoisier held many public offices in France, working in areas such as finance, agriculture, education, hygiene, and social welfare. In these capacities, he attempted to introduce various reforms, among them changes in the French monetary and tax systems, and also in farming

methods. During the French Revolution, he and other influential French leaders fell out of favor. Lavoisier was arrested in 1793. On May 8, 1794, after a trial that lasted less than a day, Lavoisier and 27 others were beheaded.

Chemical Equations Balanced Equations

A chemical equation must show the identities and relative amounts of the reactants and products. However, it can also indicate the physical states of the reactants and products, whether energy is released or absorbed, and whether a catalyst is used. A chemical equation is not accurate unless the formulas are correct and the equation is balanced.

Classifying Chemical Reactions Types of Reactions

Most chemical reactions can be classified as one of five types of reactions: synthesis, decomposition, single-displacement, double-displacement, and combustion. In a double-displacement reaction, two elements replace one another in two different compounds. Double-displacement reactions occur only in solution and only if a precipitate, a gas, or water is formed.

Charles D. Winters/Photo Researchers

section 4 Reaction Rates and Energy Chemical Reactions and Energy

Every reaction has a rate, or speed at which it proceeds. The study of reaction rates and reaction mechanisms is known as chemical kinetics. Temperature, concentration, particle size, catalysts, and the nature of the reactants determine the reaction rate. The rate of a reaction is not constant throughout the course of the reaction because the rate is proportional to reactant concentration. The concentration of reactants decreases as reactants are converted to products. In other words, as the reactants are used up to form products, the reactants cannot find one another as often as they could in the beginning of the reaction. This decreases the rate of reaction. To counteract this slowdown, an excess of one reactant is often used to keep the reaction from becoming impractically slow.

In 1888, the French chemist Henri Le Chatelier (1850–1936) set forth a simple important generalization on the behavior of equilibrium systems. This generalization, known as Le Chatelier's principle, states that if a stress is applied to a system at equilibrium, the system will shift to relieve that stress and restore equilibrium under a new set of conditions. The application of Le Chatelier's principle helps in predicting the effect of concentration, temperature, and volume on the rate of chemical reactions.

Endergonic Reactions

Catalysts are extremely important to industrial chemistry. Many industrial processes use catalysts to lower reaction temperatures, thus reducing energy costs. Once suitable catalysts are found, chemical reactions that are otherwise too slow to be of practical value may become cost-effective.

Enzymes are large proteins that act as catalysts for biological reactions. The enzyme amylase found in human digestive systems is able

to catalyze the breakdown of starch to yield glucose but has no effect on cellulose, even though the two compounds are similar. This is why humans can digest a hamburger bun, but not the grass that fed the cow.

All-American Chemistry

Few things are as American as fireworks on the Fourth of July. The explosions of color and deafening booms get huge reactions from crowds across the country. These sights and sounds are the results of chemical reactions involving various substances with oxygen.

Science Journal Describe several cause-and-effect types of events that might happen in your refrigerator. Later, decide which of the events are chemical reactions.

718

Theme Connection

Systems and Interactions Chemical reactions depend on interactions among chemical compounds. A chemical reaction can be considered to be a system into and out of which energy flows.

About the Photo

Fireworks All of the fireworks effects we enjoy, including the vibrant colors and the boom of the explosions, are the result of chemical reactions. The colors come from small amounts of metal ions—blue from copper, red from lithium, gold from sodium, and green from barium. The booms and bangs are the result of chemical reactions with oxygen.

Start-Up Activities

Launch LAB

Rusting—A Chemical Reaction

Like exploding fireworks, rusting is a chemical reaction in which iron metal combines with oxygen. Other metals combine with oxygen, too—some more readily than others. In this lab, you will compare how iron and aluminum react with oxygen.

1. Place a clean iron or steel nail in a dish prepared by your teacher.
2. Place a clean aluminum nail in a second dish. These dishes contain agar gel and an indicator that detects a reaction with oxygen.
3. Observe both nails after one hour. Record any changes around the nails in your Science Journal.
4. Carefully examine both of the dishes the next day.
5. **Think Critically** Record any differences you noticed between the two dishes. Predict if a reaction occurred. How can you tell? What might have caused the differences you observed between the two nails. Explain.

FOLDABLESTM Study Organizer

Chemical Reactions Make the following Foldable to help you classify chemical reactions.

- STEP 1** Fold a sheet of paper in half lengthwise.

- STEP 2** Mark four lines evenly spaced at even intervals down the page.

- STEP 3** Cut only the top layer along the four marks to make five tabs. Label the tabs as shown.

Classify As you read, record examples of each type of reaction from the book, then review the chapter and list other examples mentioned in the text or from classroom discussions.

Preview this chapter's content and activities at www.ck12.org/chemistry/chemical-reactions/

Launch LAB

Purpose Use this Launch Lab to introduce students to chemical reactions and to the evidence that a chemical change has occurred.

L2 ELL IS Visual-Spatial

Preparation Prepare agar by dissolving about ½ teaspoon of agar in about 240 mL of water. Heat just until boiling. Cool slightly and stir in 2 mL of 1% phenolphthalein (in alcohol) solution. Pour enough solution into the petri dishes to partly submerge the nails. Strips of aluminum cut from aluminum pie tins may be used in place of aluminum nails. **WARNING:** aluminum strips may have sharp edges. For this lab, use only uncoated nails.

Materials agar mixture, petri dishes, aluminum nails, iron nails

Teaching Strategy Ask students how we know when a chemical change has taken place. **evidence** such as color changes

Think Critically

Rusting involves many chemical reactions. Among them is the formation of iron hydroxides, which cause the phenolphthalein to turn pink. The red-brown color that appears later indicates the formation of iron(III) oxide. Aluminum reacts slowly with oxygen, but this will not be visible here.

Assessment

Process Have students use colored markers to draw the two colors observed with the iron nail. Point out that these represent two different reactions. **L2**

What You'll Learn

- Identify the reactants and products in a chemical reaction.
- Determine how a chemical reaction satisfies the law of conservation of mass.
- Determine how chemists express chemical changes using equations.

Why It's Important

Chemical reactions cook our food, warm our homes, and provide energy for our bodies.

Review Vocabulary

chemical change: change of one substance into a new substance

New Vocabulary

- chemical reaction
- reactant
- product
- chemical equation

Describing Chemical Reactions

Dark mysterious mixtures react, gas bubbles up and expands, and powerful aromas waft through the air. Where are you? You are in the kitchen baking a chocolate cake. Nowhere in the house do so many chemical reactions take place as in the kitchen.

Chemical reactions are taking place all around you and even within you. A **chemical reaction** is a change in which one or more substances are converted into new substances. The substances that react are called **reactants**. The new substances produced are called **products**.

Chemical and Nuclear Reactions When chemical reactions occur, new compounds form when bonds between atoms in the reactants break and new bonds form. Recall that chemical bonds form when outer electrons, called valence electrons, are shared between atoms or are transferred from one atom to another. As a result, only the outer electrons of atoms are involved in chemical reactions. The nucleus of an atom is not affected by a chemical reaction. An atomic nucleus changes only when nuclear decay or a nuclear reaction, such as nuclear fission or fusion, occurs. The energy released by a nuclear reaction is millions of times greater than the energy released by a chemical reaction. **Figure 1** summarizes the difference between nuclear and chemical reactions.

Figure 1 Different parts of the atom are used in chemical and nuclear reactions.

Identify how chemical bonds are formed.

Chemical reactions use electrons to form new substances.

Electron cloud

Nucleus

Nuclear reactions use the nucleus to form new substances.

Conservation of Mass

By the 1770s, chemistry was changing from the art of alchemy to a true science. Instead of being satisfied with a superficial explanation of unknown events, scientists began to study chemical reactions more thoroughly. Through such study, the French chemist Antoine Lavoisier established that the total mass of the products always equals the total mass of the reactants. This principle is illustrated in **Figure 2**.

The Father of Modern Chemistry When Lavoisier demonstrated the law of conservation of mass, he set the field of chemistry on its modern path. In fact, Lavoisier is known today as the father of modern chemistry for his more accurate explanation of the conservation of mass and for describing a common type of chemical reaction called combustion, which you will learn about later in this chapter. Lavoisier also pioneered early experimentation on the biological phenomena of respiration and metabolism that contributed early milestones in the study of biochemistry, medicine, and even sports medicine.

 **Reading Check** How did Lavoisier's contributions earn him the title of Father of Modern Chemistry?

Nomenclature Antoine Lavoisier's work led him to the conclusion that language terminology would be critical to communicate novel scientific ideas. Lavoisier began to develop the system of naming substances based on their composition that we still use today. In 1787, Lavoisier and several colleagues published *Méthode de Nomenclature Chimique* as one of the first sets of nomenclature guidelines.

Figure 2 The mass of the candles and oxygen before burning is exactly equal to the mass of the remaining candle and gaseous products.

Describe the principle that is represented in this figure.

SECTION 1 Chemical Changes 721

Reading Strategy

Clarify Text Model this strategy by reading a challenging piece of text aloud. Demonstrate that when students encounter new vocabulary or difficult concepts, they can employ clarification strategies. As you read, articulate your thoughts, reread when necessary, and show students how to use the context of the passage to help them clarify.

Differentiated Instruction

Challenge Photographs are made using a chemical reaction driven by exposure to light. Ask students to find out what metal is typically involved in the process. *Silver ions in silver bromide (AgBr) can be changed to silver metal when exposed to light.*   **Linguistic**

Caption Answer

Figure 1 Outer electrons are shared or transferred between atoms.

Activity

Table of Elements Lavoisier was an early contributor to what became the periodic table of elements. Have students use the library to find names of other scientists who helped shape and fill the table. 

IDENTIFYING Misconceptions

Nomenclature Students may think that there is only one form of nomenclature that serves all branches of science. Explain that different disciplines have different forms of specific nomenclature, but at the same time emphasize that nomenclature is consistent within each area. Also emphasize that guidelines are established to maintain consistency and uniformity and that the guidelines for nomenclature are often similar across disciplines. This makes it possible for scientists whose work crosses scientific boundaries to communicate effectively.

Reading Check

Answer He explained the theory of conservation of mass and was key in developing modern chemical nomenclature.

Caption Answer

Figure 2 law of conservation of mass

Use an Analogy

Balancing a Ledger Lavoisier's background included tax collecting and auditing. Balancing a ledger is somewhat like balancing a chemical equation. One must carefully consider what goes in and what comes out without losing anything. [L2]

Quick Demo

Conservation of Mass

Materials balance, Erlenmeyer flask, sodium carbonate, water, calcium chloride, stopper, test tube

Estimated Time 15 minutes

Procedure Add 0.50 g of sodium carbonate and 25 mL of water in the flask. Add 10 mL of water and 0.10 g of calcium chloride to a small test tube. Put the test tube in the flask. Weigh the flask and contents. Shake the stoppered flask so that the tube contents mix with the flask content. Reweigh the stoppered flask. The mass of the flask and contents remain the same. [L2]

ELL **Visual-Spatial**

Reading Check

Answer In a chemical reaction, matter is not created or destroyed.

Figure 3 Antoine Lavoisier's wife, Marie-Anne, drew this view of Lavoisier in his laboratory performing studies on oxygen. She depicted herself at the right taking notes.

Lavoisier's Contribution One of the questions that motivated Lavoisier was the mystery of exactly what happened when substances changed form. He began to answer this question by experimenting with mercury. In one experiment, Lavoisier placed a carefully measured mass of solid mercury(II) oxide, which he knew as mercury calx, into a sealed container. When he heated this container, he noted a dramatic change. The red powder had been transformed into a silvery liquid that he recognized as mercury metal, and a gas was produced. When he determined the mass of the liquid mercury and gas, their combined masses were exactly the same as the mass of the red powder he had started with.

Lavoisier also established that the gas produced by heating mercury(II) oxide, which we call oxygen, was a component of air. He did this by heating mercury metal with air and saw that a portion of the air combined to give red mercury(II) oxide. He studied the effect of this gas on living animals, including himself. Hundreds of experiments carried out in his laboratory, as shown in **Figure 3**, confirmed that in a chemical reaction, matter is not created or destroyed, but is conserved. This principle became known as the law of conservation of mass. This means that the total starting mass of all reactants equals the total final mass of all products.

Reading Check What does the law of conservation of mass state?

ScienceOnline

Topic: Antoine Lavoisier

Visit fl.gpscience.com for Web links to information about Antoine Lavoisier and his contributions to chemistry.

Activity In your Science Journal, write a brief biography of Antoine Lavoisier that includes some of his non-scientific activities and political interests, as well as his scientific contributions.

Curriculum Connection

History Have students research and write a short report about the time period in France in which Lavoisier lived (mid- to late-eighteenth century). For comparison and perspective, have them relate the same period to the happenings in America. [L2] **P** **L** **Linguistic**

Differentiated Instruction

English-Language Learners Express to the class that scientists from many countries have made significant contributions to general science. Recount the scientific contributions of the Frenchman Lavoisier and have non-English language speakers read a chemical reaction so they can recognize that the formulas and notation are the same, regardless of the language of the scientist. [L2]

Writing Equations

If you wanted to describe the chemical reaction shown in **Figure 4**, you might write something like this:

Nickel(II) chloride, dissolved in water, plus sodium hydroxide, dissolved in water, produces solid nickel(II) hydroxide plus sodium chloride, dissolved in water.

This series of words is rather cumbersome, but all of the information is important. The same is true of descriptions of most chemical reactions. Many words are needed to state all the important information. As a result, scientists have developed a shorthand method to describe chemical reactions. A **chemical equation** is a way to describe a chemical reaction using chemical formulas and other symbols. Some of the symbols used in chemical equations are listed in **Table 1**.

The chemical equation for the reaction described above in words and shown in **Figure 4** looks like this:

On the left side of the equation are the reactants, nickel(II) chloride and sodium hydroxide. On the right side of the equation are the products, nickel(II) hydroxide and sodium chloride.

It is much easier to tell what is happening by writing the information in this form. Later, you will learn how chemical equations make it easier to calculate the quantities of reactants that are needed and the quantities of products that are formed.

Figure 4 A white precipitate of nickel(II) hydroxide forms when sodium hydroxide is added to a green solution of nickel(II) chloride. Sodium chloride, the other product formed, is in solution.

Table 1 Symbols Used in Chemical Equations

Symbol	Meaning
→	produces or yields
+	plus
(s)	solid
(l)	liquid
(g)	gas
(aq)	aqueous, a substance is dissolved in water
heat	the reactants are heated
→	
light	the reactants are exposed to light
→	
elec.	an electric current is applied to the reactants
→	

Use an Analogy

Baseball Scores Have a baseball coach or interested student bring in a scorer's record book from a baseball game. The records are kept for each inning with accepted symbols for events such as strikeout (K), home run (HR), infield out made by throw from third to first base (5-3), etc. The symbols in baseball allow a great deal of information to be recorded accurately in a small space. Chemical equations do this as well. **L2** **IS** **Logical-Mathematical**

Discussion

Burning Copper Burning a piece of copper in a flame will produce a product that has a greater mass than the original copper. Why doesn't this violate the law of conservation of mass? **The mass of oxygen participating in the burning process must be included as part of the mass of the reactants.** **L2** **IS** **Logical-Mathematical**

Fun Fact

Lavoisier was an early advocate of the use of chemical equations. He used symbols to show both the identity and quantity of materials in reactions and thought that algebra was the best language for expressing scientific information. He wrote, "In order to show at a glance the results of what happens . . . I have constituted formulae of a kind that could at first be taken for algebraic formulae . . ."

Science Journal

Soda Coefficients Have students calculate the total amount of soft drink in two 2-L bottles, three six-packs of 355-mL cans, and one case of 355-mL cans. **Total = 4,000 + 6,390 + 8,520 = 18,910 mL.** The coefficients in *2 bottles*, *3 six-packs*, and *1 case* indicate the number of packaged units. Coefficients in a chemical equation indicate the number of units of atoms. **L2**

Teacher FYI

Chemist Symbols Some chemists use the symbol (cr) to represent solids that are crystals and (amor) to represent amorphous solids, which have no definite structure.

Mini LAB

Video Lab available.

Purpose Students see that coefficients are not conserved in a chemical equation but that mass is. **Logical-Mathematical**

Materials 15 index cards per student, markers

Safety Precautions Request assistance from a parent or guardian.

Teaching Strategy Suggest students redo the activity, varying the composition of a team.

Analysis

1. G_2F_2C ; 2 guards + 2 forwards + 1 center $\rightarrow$ 1 team
2. The equation uses coefficients like a chemical equation, and it shows conservation of mass. Only a specific number of each type of player can be used per team. Those left over sit on the bench (cannot be used).
3. The total number of cards at the beginning equals the number of leftover cards plus the cards being used for the team.

Assessment

Oral Ask students how many guards would be needed to make four teams. $4 \times 2 = 8$ How many complete teams could be made around 5 centers? $5 \times 1 = 5$ teams How many players would be left over when the following players assembled to make teams: 10 guards, 9 forwards, and 5 centers? $\frac{9}{2} = 4$ teams with 1 extra forward, 1 extra center, 2 extra guards Use PASC, p. 101.

Reading Check

Answer They act as unit managers, representing the number of units of each substance taking part in a reaction.

Mini LAB

Designing a Team Equation

Procedure

1. Obtain 15 index cards and mark each as follows: five with *Guard*, five with *Forward*, and five with *Center*.
2. Group the cards to form as many complete basketball teams as possible. Each team needs two guards, two forwards, and one center.

Analysis

1. Write the formula for a team. Write the formation of a team as an equation. Use coefficients in front of each type of player needed for a team.
2. How is this equation like a chemical equation? Why can't you use the remaining cards?
3. How do the remaining cards illustrate the law of conservation of matter in this example?

Unit Managers

What do the numbers to the left of the formulas for reactants and products mean? Remember that according to the law of conservation of mass, matter is neither made nor lost during chemical reactions. Atoms are rearranged but never lost or destroyed. These numbers, called coefficients, represent the number of units of each substance taking part in a reaction. Coefficients can be thought of as unit managers.

Reading Check

What is the function of coefficients in a chemical equation?

Imagine that you are responsible for making sandwiches for a picnic. You have been told to make a certain number of three kinds of sandwiches, and that no substitutions can be made. You would have to figure out exactly how much food to buy so that you had enough without any food left over. You might need two loaves of bread, four packages of turkey, four packages of cheese, two heads of lettuce, and ten tomatoes. With these supplies you could make exactly the right number of each kind of sandwich.

In a way, your sandwich-making effort is like a chemical reaction. The reactants are your bread, turkey, cheese, lettuce, and tomatoes. The number of units of each ingredient are similar to the coefficients of the reactants in an equation. The sandwiches are similar to the products, and the numbers of each kind of sandwich are similar to the coefficients.

Knowing the number of units of reactants enables chemists to add the correct amounts of reactants to a reaction. Also, these units, or coefficients, tell them exactly how much product will form. An example of this is the reaction of one unit of $NiCl_2$ with two units of $NaOH$ to produce one unit of $Ni(OH)_2$ and two units of $NaCl$. You can see these units in **Figure 5**.

Figure 5 Each coefficient in the equation represents the number of units of each type in this reaction.

Visual Learning

Figure 5 Have students count the atoms in the illustration and match them with the formulas in the equation. Point out which atoms combine to form each product. **Visual-Spatial**

Post Reading

Science Journal Have students respond to the following prompt in their Science Journals: What did you learn by reading about chemical reactions, chemical equations, and the law of conservation of mass? Encourage students to include their own opinions and thoughts regarding what they read.

IUPAC Antoine Lavoisier and his colleagues understood the importance of using a nomenclature system that helps scientists communicate their data. Since that time, the guidelines have continued to evolve with scientific discovery. In 1919, the International Union of Applied Chemistry (IUPAC) was formed. The primary mission of the IUPAC is to coordinate guidelines for naming chemical compounds systematically. **Figure 6** illustrates some of the early events in nomenclature development.

In addition to chemical nomenclature, IUPAC also is responsible for standardizing chemistry methods, evaluating atomic weights and environmental programs, along with many other areas relating to chemistry.

Figure 6 This time line of nomenclature development and publications does not end in 1957. In fact, today there are nomenclature organizations for almost every branch of scientific study, and the rules and guidelines for naming substances continue to evolve.

Content Background

IUPAC is an international organization with one mission of promoting free exchange of scientific information. There are 65 countries whose scientists are affiliated with IUPAC. Countries such as Croatia and the Netherlands are members of IUPAC.

DAILY INTERVENTION

Check for Understanding

Chemistry Flashcards Create a set of chemistry flashcards by writing the chemical formulas for a variety of substances on standard index cards. Also write several forward-pointing arrows on some cards. Have students create basic chemical reactions demonstrating the concept of “reactants produce products”. Remember when creating the flashcards to include appropriate product substances to pair with the reactants. **L2**

Reteach

Understanding Coefficients Show that the balanced equation for the decomposition of water is $2\text{H}_2\text{O} \rightarrow 2\text{H}_2 + \text{O}_2$. Ask students to use the coefficients to determine the number of hydrogen and oxygen atoms on each side of the equation. **4 hydrogens and 2 oxygens on the left side and 4 hydrogens and 2 oxygens on the right side** **L1 LS Logical-Mathematical**

section 1 review

Summary

Describing Chemical Reactions

- A chemical reaction is a process that involves one or more reactants changing into one or more products.
- In chemical reactions and nuclear reactions, different parts of the atom form new substances.

Conservation of Mass

- A basic principle of chemistry is that matter, during a chemical change, can neither be created nor destroyed.

Writing Equations

- Chemical equations describe the change of reactants to products and obey the law of conservation of mass.

Unit Managers

- Coefficients represent how many units of each substance are involved in a chemical reaction.

Self Check

1. **Identify** the reactants and the products in the following chemical equation.
 $\text{Cd}(\text{NO}_3)_2(\text{aq}) + \text{H}_2\text{S}(\text{g}) \rightarrow \text{CdS}(\text{s}) + 2\text{HNO}_3(\text{aq})$
2. **Identify** the state of matter of each substance in the following reaction.
 $\text{Zn}(\text{s}) + 2\text{HCl}(\text{aq}) \rightarrow \text{H}_2(\text{g}) + \text{ZnCl}_2(\text{aq})$
3. **Compare and contrast** a chemical reaction and a nuclear reaction.
4. **Explain** the importance of the law of conservation of mass.
5. **Think Critically** How would global communication between scientists have been changed if IUPAC had not been established?

Applying Math

6. **Solve One-Step Equations** When making soap, if 890 g of a specific fat react completely with 120 g of sodium hydroxide, the products formed are soap and 92 g of glycerin. Calculate the mass of soap formed to satisfy the law of conservation of mass.

section 1 review

1. reactants: $\text{Cd}(\text{NO}_3)_2$ and H_2S ; products: CdS and HNO_3
2. Zn is a solid, HCl is dissolved in water, H_2 is a gas, and ZnCl_2 is dissolved in water.
3. Both reactions produce a change, resulting in a new product. In a

chemical reaction, the electrons are rearranged to create new bonds. In a nuclear reaction, the nucleus of the atom is changed.

4. The law of conservation of mass explains why matter in the universe does not go away permanently.

5. Scientists from different countries would have a difficult time discussing discoveries due to a lack of a common language.
6. $890 + 120 = 1,010$ g of reactant, which must equal 1,010 g of product; $1,010 - 92 = 918$ g of soap.

Assessment

Performance Have students examine this unbalanced equation for the rusting of iron ($\text{Fe} + \text{O}_2 + \text{H}_2\text{O} \rightarrow \text{Fe}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$) to determine the products and reactants and use coefficients to balance the equation. $4\text{Fe} + 3\text{O}_2 + 6\text{H}_2\text{O} \rightarrow 2\text{Fe}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$ Use PASC, p. 101. **L2**

Tie to Prior Knowledge

Building Blocks Ask students if they remember attachable plastic building blocks. Remind students that the structures could be disassembled to make different objects from the same blocks. In a similar way, a balanced chemical equation represents the rearrangement of a set of atoms into new compounds.

Word Analysis The new vocabulary term *balanced chemical equation* is composed of three words. Have students determine the meaning of each word. Then ask them to predict the meaning of the whole term. As they read, students may verify or modify their understanding of the term.

Reading Guide

What You'll Learn

- Identify what is meant by a balanced chemical equation.
- Determine how to write balanced chemical equations.

Why It's Important

Chemical equations are the language used to describe chemical change, which allow scientists to develop products for our world.

Review Vocabulary

subscript: in a chemical formula, a number below and to the right of a symbol indicating number of atoms

New Vocabulary

- balanced chemical equation

Balanced Equations

Lavoisier's mercury(II) oxide reaction, shown in Figure 7, can be written as:

Figure 7 Mercury metal forms when mercury oxide is heated. Because mercury is poisonous, this reaction is never performed in a classroom laboratory.

Notice that the number of mercury atoms is the same on both sides of the equation but that the number of oxygen atoms is not the same. One oxygen atom appears on the reactant side of the equation and two appear on the product side.

Atoms	HgO	→	Hg	+	O ₂
Hg	1		1		
O	1				2

But according to the law of conservation of mass, one oxygen atom cannot just become two. Nor can you simply add the subscript 2 and write HgO₂ instead of HgO. The formulas HgO₂ and HgO do not represent the same compound. In fact, HgO₂ does not exist. The formulas in a chemical equation must accurately represent the compounds that react.

Fixing this equation requires a process called balancing. Balancing an equation doesn't change what happens in a reaction—it simply changes the way the reaction is represented. The balancing process involves changing coefficients in a reaction to achieve a **balanced chemical equation**, which has the same number of atoms of each element on both sides of the equation.

Choosing Coefficients Finding out which coefficients to use to balance an equation is often a trial-and-error process. In the equation for Lavoisier's experiment, the number of mercury atoms is balanced, but one oxygen atom is on the left and two are on the right. If you put a coefficient of 2 before the HgO on the left, the oxygen atoms will be balanced, but the mercury atoms become unbalanced. To balance the equation, also put a 2 in front of mercury on the right. The equation is now balanced.

Balancing Equations Magnesium burns with such a brilliant white light that it is often used in emergency flares as shown in **Figure 8**. Burning leaves a white powder called magnesium oxide. To write a balanced chemical equation for this and most other reactions, follow these four steps.

Step 1 Write a chemical equation for the reaction using formulas and symbols. Recall that oxygen is a diatomic molecule.

Step 2 Count the atoms in reactants and products.

The magnesium atoms are balanced, but the oxygen atoms are not. Therefore, this equation isn't balanced.

Step 3 Choose coefficients that balance the equation. Remember, never change subscripts of a correct formula to balance an equation. Try putting a coefficient of 2 before MgO.

Step 4 Recheck the numbers of each atom on each side of the equation and adjust coefficients again if necessary. Now two Mg atoms are on the right side and only one is on the left side. So a coefficient of 2 is needed for Mg to balance the equation.

Reading Check How can you balance a chemical equation using coefficients?

Science Online

Topic: Balancing Chemical Equations

Visit fl.gpescience.com for Web links to information about balancing chemical equations.

Activity Using the Web links, locate a website that offers practice problems for balancing chemical equations. Copy several of the unbalanced equations in your Science Journal and try to balance them. Check your work against the answers on the web site when you are done.

Figure 8 Magnesium combines with oxygen, giving an intense white light.

SECTION 2 Chemical Equations 727

Teacher FYI

Calculating Fractions Fractions can be used to balance chemical equations. $\text{Na} + \text{Cl}_2 \rightarrow \text{NaCl}$ can be balanced as $2\text{Na} + \text{Cl}_2 \rightarrow 2\text{NaCl}$ or as $\text{Na} + \frac{1}{2}\text{Cl}_2 \rightarrow \text{NaCl}$. Fractions are used mainly when the calculations involve the formation of only one unit of a product.

Fun Fact

Air bags should really be called nitrogen bags. They are not filled with air, but with nitrogen.

Reading Check

Answer by a trial-and-error process, then by counting the number of atoms of reactant and product molecules

Reading Strategy

Synthesize and Summarize

Have students summarize the steps required to balance a chemical equation. Remind them that they should put ideas together in a condensed form using their own words. This requires synthesizing. Ask students to include an example in their summaries to help clarify.

Discussion

Balancing Strategies Discuss with the class various techniques or strategies that might be helpful for students to visualize the number of atoms on each side of the equation and work through the process of assigning coefficients. Encourage students to share their individual processes.

Differentiated Instruction

Learning Disabled The concept of coefficients may be difficult for students to understand. Take time to relate the use of coefficients in chemical equations to the students' mathematics experience. In this instruction use simple, non-chemical examples to illustrate the concept of coefficients.

Challenge Safety air bags in automobiles depend on a chemical reaction to inflate. Have students supply the coefficients needed to balance the equation: $\text{NaN}_3(s) \rightarrow \text{Na}(g) + \text{N}_2(g)$

Applying Math

Math Standards

National: 1, 2, 9, 10

Florida: MA.D.2.4.1

Answers to Practice Problems

- $2\text{HCl} + \text{Na}_2\text{CO}_3 \rightarrow 2\text{NaCl} + \text{H}_2\text{O} + \text{CO}_2$
- $2\text{NaOH} + \text{CaBr}_2 \rightarrow \text{Ca(OH)}_2 + 2\text{NaBr}$

IDENTIFYING

Misconceptions

Students may think that when the body of a car rusts away, leaving holes in the metal, that the law of conservation of matter is not obeyed. Explain that the corrosion of iron in the presence of water and oxygen in fact does obey the law, and reinforce this fact by introducing the chemical equation for the oxidation of iron: $4\text{Fe(s)} + 3\text{O}_2\text{(g)} \rightarrow 2\text{Fe}_2\text{O}_3\text{(s)}$.

Virtual Labs

In Balance What is a balanced chemical equation?

Applying Math

Use Coefficients

BARIUM SULFATE REACTION A sample of barium sulfate is placed on a piece of paper, which is then ignited. Barium sulfate reacts with the carbon from the burned paper producing barium sulfide and carbon monoxide. Write a balanced chemical equation for this reaction.

IDENTIFY known values

We know the substances that are involved in the reaction. From this, we can write a chemical equation showing reactants and products.

SOLVE the problem

The chemical equation above is not balanced. There are more oxygen atoms on the left side of the equation than there are on the right side. This must be corrected while keeping all other atom counts in balance. Begin to balance the equation by first counting and listing the atoms before and after the reaction.

Kind of Atom	Number of Atoms Before Reaction	Number of Atoms After Reaction
Ba	1	1
S	1	1
O	4	1
C	1	1

Next, adjust the coefficients until all atoms are balanced on the left and right sides of the arrow. Try putting a 4 in front of CO. Now you have 4 oxygen atoms on the right, which balances on both sides, but the carbon atoms become unbalanced. To fix this, add a 4 in front of the C in the reactants. The balanced equation looks like this:

CHECK your answer

Count the number of atoms on each side of the equation and verify that they are equal.

Practice Problems

- Balance this equation: $\text{NaOH(aq)} + \text{CaBr}_2\text{(aq)} \rightarrow \text{Ca(OH)}_2\text{(s)} + \text{NaBr(aq)}$.
- HCl is slowly added to aqueous Na_2CO_3 forming NaCl , H_2O , and CO_2 . Follow the steps above to write a balanced equation for this reaction.

For more practice problems, go to page 879, and visit Math Practice at fl.gpescience.com.

Post Reading

Fix-Up Strategy Model this strategy by going back to a challenging section of text. Articulate your thoughts. Make a connection between real-world concepts and the material in the text. Predict, stop to think, visualize, retell what you've read, and reread. Allow students to practice this strategy with a partner.

Polish Your Skill When lithium metal is treated with water, hydrogen gas and lithium hydroxide are produced, as shown in Figure 9.

Step 1 Write the chemical equation.

Step 2 Check for balance by counting the atoms.

Atoms	Li	+	H ₂ O	→	LiOH	+	H ₂
Li	1				1		
H			2		1		2
O			1		1		

This equation is not balanced. There are three hydrogen atoms on the right and only two on the left. Complete steps 3 and 4 to balance the equation. After each step, count the atoms of each element. When equal numbers of atoms of each element are on both sides, the equation is balanced. The balanced chemical equation looks like this:

The coefficients and subscripts are multiplied together, not added, to determine the correct number of atoms for each element.

Figure 9 When lithium metal is added to water, it reacts, producing a solution of lithium hydroxide and bubbles of hydrogen gas.

3 Assess

DAILY INTERVENTION

Check for Understanding

Logical-Mathematical Bring a disposable butane lighter to class. Write the formula for butane, C_4H_{10} , on the chalkboard, and as you light the lighter, ask students to identify the chemical reaction taking place. **Oxygen is combining with the carbon and hydrogen to produce water and carbon dioxide.** Have them write and balance the equation for the reaction. $2\text{C}_4\text{H}_{10} + 13\text{O}_2 \rightarrow 8\text{CO}_2 + 10\text{H}_2\text{O}$ **L3 IS**

Reteach

Molecular View Using the style of Figure 5, draw on the chalkboard the structures of $\text{Ca}(\text{OH})_2$, H_3PO_4 , $\text{Ca}_3(\text{PO}_4)_2$, and H_2O . Tell students that calcium hydroxide reacts with hydrogen phosphate to produce calcium phosphate and water. Ask students to write the balanced chemical equation for this reaction. $3\text{Ca}(\text{OH})_2 + 2\text{H}_3\text{PO}_4 \rightarrow \text{Ca}_3(\text{PO}_4)_2 + 6\text{H}_2\text{O}$ **L2 IS Visual-Spatial**

Assessment

Performance Have students draw Venn diagrams to contrast the changes in chemical reactions with those in nuclear reactions. **In a chemical change, the atoms do not change their basic identity. In nuclear changes, the identity of an atom is often changed.** Use PASC, p. 167.

P L3

section 2 review

Summary

Balanced Equations

- A chemical equation is a way to indicate reactants and products and relative amounts of each.
- A balanced chemical equation tells the exact number of atoms involved in the reaction.
- Balanced chemical equations must satisfy the law of conservation of matter; no atoms of reactant or product can be lost from one side to the other.
- Coefficients are used to achieve balance in a chemical equation.
- Chemical equations cannot be balanced by adjusting the subscript numerals in compound names because doing so would change the compounds.

Self Check

1. **Describe** two reasons for balancing chemical equations.
2. **Balance** this chemical equation: $\text{Fe}(s) + \text{O}_2(g) \rightarrow \text{FeO}(s)$.
3. **Explain** why oxygen gas must always be written as O_2 in a chemical equation.
4. **Infer** What coefficient is assumed if no coefficient is written before a formula in a chemical equation?
5. **Think Critically** Explain why the sum of the coefficients on the reactant side of a balanced equation does not have to equal the sum of the coefficients on the product side of the equation.

Applying Math

6. **Use Numbers** Balance the equation for the reaction $\text{Fe}(s) + \text{Cl}_2(g) \rightarrow \text{FeCl}_3(s)$.

What You'll Learn

- **Identify** the five general types of chemical reactions.
- **Identify** redox reactions.
- **Predict** which metals will replace other metals in compounds.

Why It's Important

Classifying chemical reactions helps to understand what is happening and predict the outcome of reactions.

Review Vocabulary

states of matter: the physical forms in which all matter naturally exists, most commonly solid, liquid, and gas

New Vocabulary

- combustion reaction
- synthesis reaction
- decomposition reaction
- single-displacement reaction
- double-displacement reaction

Types of Reactions

You might have noticed that there are all sorts of chemical reactions. In fact, there are literally millions of chemical reactions that occur every day, and scientists have described many of them and continue to describe more. With all these reactions, it would be impossible to use the information without first having some type of organization. With this in mind, chemists have defined five main categories of chemical reactions: combustion, synthesis, decomposition, single displacement, and double displacement.

Combustion Reactions If you have ever observed something burning, you have observed a combustion reaction. As mentioned previously, Lavoisier was one of the first scientists to accurately describe combustion. He deduced that the process of burning (combustion) involves the combination of a substance with oxygen. A **combustion reaction** occurs when a substance reacts with oxygen to produce energy in the form of heat and light. Combustion reactions also produce one or more products that contain the elements in the reactants. For example, the reaction between carbon and oxygen produces carbon dioxide. Many combustion reactions also will fit into other categories of reactions. For example, the reaction between carbon and oxygen also is a synthesis reaction.

Figure 10 Rust has accumulated on the *Titanic* since it sank in 1912. **Identify** the general formula for a **synthesis reaction**.

Transparency Activity, p. 48

Directed Reading for Content Mastery, p. 21

Enrichment, p. 33

Home and Community Involvement, p. 33

Synthesis Reactions One of the easiest reaction types to recognize is a synthesis reaction. In a **synthesis reaction**, two or more substances combine to form another substance. The generalized formula for this reaction type is as follows: $A + B \rightarrow AB$.

The reaction in which hydrogen burns in oxygen to form water is an example of a synthesis reaction.

This reaction is used to power some types of rockets. Another synthesis reaction is the combination of oxygen with iron in the presence of water to form hydrated iron(II) oxide or rust. This reaction is shown in **Figure 10**.

Decomposition Reactions A decomposition reaction is just the reverse of a synthesis. Instead of two substances coming together to form a third, a **decomposition reaction** occurs when one substance breaks down, or decomposes, into two or more substances. The general formula for this type of reaction can be expressed as follows: $AB \rightarrow A + B$.

Most decomposition reactions require the use of heat, light, or electricity. An electric current passed through water produces hydrogen and oxygen as shown in **Figure 11**.

Single Displacement When one element replaces another element in a compound, it is called a **single-displacement reaction**. Single-displacement reactions are described by the general equation $A + BC \rightarrow AC + B$. Here you can see that atom A displaces atom B to produce a new molecule AC. A single displacement reaction is illustrated in **Figure 12**, where a copper wire is put into a solution of silver nitrate. Because copper is a more active metal than silver, it replaces the silver, forming a blue copper(II) nitrate solution. The silver, which is not soluble, forms on the wire.

Reading Check Describe a single-displacement reaction.

Figure 11 Water decomposes into hydrogen and oxygen when an electric current is passed through it. A small amount of sulfuric acid is added to increase conductivity. Notice the proportions of the gases collected.

Describe how this is related to the coefficients of the products in the equation.

Figure 12 Copper in a wire replaces silver in silver nitrate, forming a blue-tinted solution of copper(II) nitrate.

2 Teach

Caption Answer

Figure 10 $A + B \rightarrow AB$

Figure 11 There are twice as many molecules of hydrogen being produced than molecules of oxygen. The coefficient of hydrogen is 2 and the coefficient of oxygen is 1.

Reading Check

Answer One element replaces another in a compound.

Activity

Building Reactions Bring in a set of connecting, colored blocks and ask students to demonstrate the five types of chemical reactions using the blocks as the reactants and products. For example, they might combine a blue block with a red block to demonstrate a synthesis reaction or start with two blocks combined and separate them to demonstrate a decomposition reaction. Encourage capable students to use more than three or four blocks to demonstrate more complex reactions. **L2**

Quick Demo Synthesis Reaction

Materials magnesium ribbon, Bunsen burner and lighter, tongs, crucible or glass catch plate

Estimated Time 15 minutes

Procedure Demonstrate the synthesis of magnesium oxide by burning magnesium ribbon in oxygen. Using tongs, position a small piece of magnesium ribbon in the flame of the Bunsen burner. *Hold the magnesium away from you and do NOT look directly into the flame.* Place the magnesium over a crucible or glass plate as it is burning to catch the ash (MgO). Reinforce the demonstration with the balanced chemical equation for the reaction: $2\text{Mg}(\text{s}) + \text{O}_2(\text{g}) \rightarrow 2\text{MgO}(\text{s})$.

Visual Learning

Figure 12 Ask students if the copper replacement of silver could have any practical use. *It is a good way to retrieve silver for recycling.* **L2** **IS** **Logical-Mathematical**

Reading Strategy

Shared Reading Read the section Synthesis Reactions aloud to the class. Draw attention to headings, figures, and equations. Ask questions, clarify, and summarize as you read. Allow student volunteers to read other sections to small groups of four to five students as they practice effective reading strategies.

Discussion

Double-Displacement Reaction

Refer to the Teacher to Teacher idea at the beginning of this chapter in which a chemical reaction created a gas that extinguished a candle. Discuss how this is a double-displacement reaction.

Make a Model

Electron Transfer Have students use themselves as model components to illustrate electron transfer in a redox reaction. Arrange several “electron” students around two nuclei, then have one or two of the “electrons” move over to the other atom. Describe how this model proves that a loss of electrons equals a gain of electrons somewhere else and that matter is neither created nor destroyed when electrons move. [L2]

✓ Reading Check

Answer Double-displacement reactions frequently produce a precipitate.

Use an Analogy

Basketball Before a basketball game, the coach assembles the players and selects five to form the starting team. Which one of the four reactions does this resemble?

synthesis One of the starting players on the basketball team fouls out of the game. The coach then substitutes a player from the bench into the game. Which one of the four reaction types does this resemble? **single displacement**

[L2] [LS] **Logical-Mathematical**

Figure 13 This figure shows the activity series of metals. A metal will replace any other metal that is less active.

The Activity Series Sometimes single-displacement reactions can cause problems. For example, if iron-containing vegetables such as spinach are cooked in aluminum pans, aluminum can displace iron from the vegetable. This causes a black deposit of iron to form on the sides of the pan. For this reason, it is better to use stainless steel or enamel cookware when cooking spinach.

We can predict which metal will replace another using the diagram shown in **Figure 13**, which lists metals according to how reactive they are. A metal can replace any metal below it on the list but not above it. Notice that copper, silver, and gold are the least active metals on the list. That is why these elements often occur as deposits of the relatively pure element. For example, gold is sometimes found as veins in quartz rock. Copper is found in pure lumps known as native copper. Other metals can occur as compounds.

Double Displacement In a **double-displacement reaction**, the positive ion of one compound replaces the positive ion of the other to form two new compounds. A double-displacement reaction takes place if a precipitate, water, or a gas forms when two ionic compounds in solution are combined. A precipitate is an insoluble compound that comes out of solution during this type of reaction. The generalized formula for this type of reaction is as follows: $AB + CD \rightarrow AD + CB$.

✓ Reading Check What type of reaction produces a precipitate?

The reaction of barium nitrate with potassium sulfate is an example of this type of reaction. A precipitate—barium sulfate—forms, as shown in **Figure 14**. The chemical equation is as follows:

These are a few examples of chemical reactions classified into types. Many more reactions of each type occur around you.

Figure 14 Solid barium sulfate settles to the bottom of a test tube containing potassium nitrate.

Observe Has a chemical change occurred in this photo? How can you tell?

732 CHAPTER 23 Chemical Reactions

Differentiated Instruction

Learning Disabled Use visual learning techniques to describe the five main types of chemical reactions. Brightly colored blocks can be used to represent reactants products, and the reactions can be demonstrated physically in addition to the explanations in the text and teacher lectures. [L1]

Challenge Many single-displacement reactions involve oxidation and reduction. Challenge students to determine the importance of the two terms in determining the activity of a metal. **Oxidation refers to losing electrons; reduction refers to gaining electrons. Chemical activity for metals usually involves the exchange of electrons. Active metals give up their electrons, or oxidize, easily.** [L3] [LS] **Linguistic**

Oxidation-Reduction Reactions One characteristic that is common to many chemical reactions is the tendency of the substances to lose or gain electrons. Chemists use the term oxidation to describe the loss of electrons and the term reduction to describe the gain of electrons. Chemical reactions involving electron transfer of this sort often involve oxygen, which is very reactive, pulling electrons from metallic elements. Corrosion of metal is a visible result, as shown in **Figure 15**.

The cause and effect of oxidation and reduction can be taken one step further by describing the substances after the electron transfer. The substance that gains an electron or electrons obviously becomes more negative, so we say it is reduced. On the other hand, the substance that loses an electron or electrons then becomes more positive, and we say it is oxidized. The electrons that were pulled from one atom were gained by another atom in a chemical reaction called reduction. Reduction is the partner to oxidation; the two always work as a pair, which is commonly referred to as redox.

Figure 15 One of the results of all of these electrons moving from one place to another might show up on the metal body of a tanker.

Caption Answer

Figure 14 Yes; a precipitate (barium sulfate) forms as a result of the reaction.

Post Reading

Essay Writing Ask students to choose a class of chemical reactions. Students will research the reaction type and compose an essay that includes a description of the reaction, including examples.

3 Assess

DAILY INTERVENTION

Reteach

Play Cards Ask students to review the following four kinds of chemical reactions by using colored note cards. Synthesis: Tape two different colored cards together. Decomposition: Two cards that are taped could be pulled apart. Single-displacement: Two different cards are taped together and a third colored card replaces one of them. Double-displacement: Two cards, from each of two sets of two different colored, taped cards are traded. [L3] **ELL** **IS** Kinesthetic

section 3 review

Summary

Types of Reactions

- Lavoisier was one of the first scientists to accurately describe a combustion reaction.
- For single-displacement reactions, we can predict which metal will replace another by comparing the activity characteristic of each.
- Some reactions produce a solid called a precipitate when two ionic substances are combined.
- Chemical reactions are organized into five basic classes: combustion, synthesis, decomposition, single displacement, and double displacement.

Oxidation-Reduction Reactions

- Oxidation is the loss of electrons and reduction is the corresponding gain of electrons.
- Redox reactions often result in corrosion and rust.
- A substance that gains electrons is reduced, and a substance that loses electrons is oxidized.

Self Check

1. **Classify** each of the following reactions:
 - a. $\text{CaO}(s) + \text{H}_2\text{O} \rightarrow \text{Ca}(\text{OH})_2(aq)$
 - b. $\text{Fe}(s) + \text{CuSO}_4(aq) \rightarrow \text{FeSO}_4(aq) + \text{Cu}(s)$
 - c. $\text{NH}_4\text{NO}_3(s) \rightarrow \text{N}_2\text{O}(g) + 2\text{H}_2\text{O}(g)$
2. **Describe** what happens in a combustion reaction.
3. **Explain** the difference between synthesis and decomposition reactions.
4. **Determine**, using **Figure 13**, if zinc will displace gold in a chemical reaction and explain why or why not.
5. **Think Critically** In the reaction $2\text{Na} + \text{Cl}_2 \rightarrow 2\text{NaCl}$, which atom is reduced and which atom is oxidized?

Applying Math

6. **Use Proportions** The following chemical equation is balanced, but the coefficients used are larger than necessary. Rewrite this balanced equation using the smallest coefficients.

$$9\text{Fe}(s) + 12\text{H}_2\text{O}(g) \rightarrow 3\text{Fe}_3\text{O}_4(s) + 12\text{H}_2(g)$$
7. **Use Coefficients** Sulfur trioxide, (SO_3), a pollutant released by coal-burning plants, can react with water in the atmosphere to produce sulfuric acid, H_2SO_4 . Write a balanced equation for this reaction.

section 3 review

1. (a) synthesis (b) single displacement (c) decomposition
2. A substance combines with oxygen to produce energy.
3. Synthesis involves bringing elements or compounds together.
4. Zinc will displace gold because zinc is more reactive than gold.
5. reduced – Cl; oxidized – Na

Decomposition involves breaking compounds down.

MA.D.2.4.1

New Vocabulary

- activation energy
- endothermic reaction
- exothermic reaction
- rate of reaction
- catalyst
- inhibitor

Chemical Reactions and Energy

Often a crowd gathers to watch a building being demolished using dynamite. In a few breathtaking seconds, tremendous structures of steel and cement that took a year or more to build are reduced to rubble and a large cloud of dust. A dynamite explosion, as shown in Figure 16, is an example of a rapid chemical reaction.

All chemical reactions release or absorb energy. This energy can take many forms, such as heat, light, sound, or electricity. The heat produced by a wood fire and the light emitted by a glow stick are two examples of reactions that release energy.

Conservation of Energy in Chemical Reactions

According to the law of conservation of energy, energy cannot be created or destroyed, but can only change form. In compounds, chemical potential energy is stored in chemical bonds between atoms. In some chemical reactions, chemical potential energy is changed to other forms of energy, such as heat or light, and is released. In other chemical reactions, forms of energy such as heat or light are converted to chemical potential energy and stored in bonds that form, and energy is absorbed. In all chemical reactions, energy is never created or destroyed, but only changes form. All reactions follow the laws of conservation of mass and energy.

Figure 16 When its usefulness is over, a building is sometimes demolished using dynamite. Dynamite charges must be placed carefully so that the building collapses inward, where it cannot harm people or property.

Reinforcement, p. 30

Physical Science Critical Thinking/Problem Solving, p. 14

Activation Energy

As you learned earlier, atoms and molecules have to bump into each other before a product can be formed. In order to form new bonds, atoms have to be close together. In addition to being close, the reactants require a certain amount of energy in order to allow the reaction to start. This minimum amount of energy needed to start a reaction is called **activation energy**. If there is not enough energy, the reaction will not start. Spilled gasoline does not ignite unless there is an energy source. Once ignited, the gasoline releases enough energy to keep going. Activation energy, which differs from reaction to reaction, is required for both exothermic and endothermic reactions.

Endergonic Reactions

Sometimes a chemical reaction requires more energy to break bonds than is released when new ones are formed. These reactions are called endergonic reactions. The energy absorbed can be in the form of light, heat, or electricity.

Electricity is often used to supply energy to endergonic reactions. For example, electroplating deposits a coating of metal onto a surface.

Heat Absorption When the energy needed is in the form of heat, the reaction is called an **endothermic reaction**. The term *endothermic* is not just related to chemical reactions. It also can describe physical changes. The process of dissolving a salt in water is a physical change. If you ever had to soak a swollen ankle in an Epsom salt solution, you probably noticed that when you mixed the Epsom salt in water, the solution became cold. The dissolving of Epsom salt absorbs heat. Thus, it is a physical change that is endothermic.

Some reactions are so endothermic that they can cause water to freeze. One such endothermic reaction is that of barium hydroxide ($\text{Ba}(\text{OH})_2$) and ammonium chloride (NH_4Cl) in water, shown in **Figure 17**.

Figure 17 As an endothermic reaction happens, such as the reaction of barium hydroxide and ammonium chloride, energy from the surrounding environment is absorbed, causing a cooling effect. Here, the reaction absorbs so much heat that a drop of water freezes and the beaker holding the reaction sticks to the wood.

SECTION 4 Reaction Rates and Energy 735

Controlling Body Heat

Some animals, such as birds, are classified as endotherms because their body temperature remains constant. An animal whose body temperature varies with its environment, such as a reptile, is classified as an ectotherm. What other animals that can be classified as ectotherms?

2 Teach

Activity

Hand Warmers Obtain several packaged hand warmers used for outdoor activities from a sports supply store. Have students carefully follow the directions and observe the results. Place the hand warmers around a small beaker of water and measure the temperature change in the water. What causes heat to be released? Many such packaged devices have a sealed sample of iron that slowly combines with oxygen (rusts) after the seal is broken and releases more heat than is required to get the reaction started. **L2**

ELL **IS** Kinesthetic

Use Science Words

Word Meanings Ask students to break the words *endergonic* and *exergonic* down into parts, and find out what each part means. Have them then explain why the words are appropriate for describing chemical processes that release or require energy. **Ex-ergon-ic:** *ex-* out of, *ergon-* work, *-ic* - having the character of. **End-ergon-ic:** *end-* into, *ergon-* work, *-ic* - having the character of. An exergonic reaction produces energy that can do work. An endergonic reaction requires energy, or work, in order to occur. **L2** **IS** Linguistic

Controlling Body Heat Both birds and mammals are endotherms. Endotherms have internal processes that maintain a constant body temperature. The internal processes cool endotherms if they are too warm, and warm them if they are too cool. **Amphibians** are ectotherms, such as frogs, toads, and salamanders.

Active Reading

Bubble Map Using a bubble map helps students start ideas flowing about a given topic. Words are clustered to describe a topic or idea that is studied. Students can use a bubble map for a prewriting, to generate ideas before writing in their Science Journals, or to review for a test. Have students design a bubble map for energy exchanges in chemical reactions. **L2**

Teacher FYI

Tracking Energy A cold pack absorbs heat as ammonium nitrate dissolves. The dissolving process usually is considered a physical change, not a chemical reaction. In most changes, the energy can be tracked as it moves from the surroundings to the system and vice versa. In the cold pack, the system is the chemical dissolving in water. The surroundings are the plastic bag, the air, any injured body area, etc.

Visual Learning

Figure 19 Bring in several glow sticks and demonstrate the reaction. Be sure to quiet the class so they can hear the containers breaking inside the sticks. When the reaction is taking place, monitor how long it takes for the glow to be visible and how long it lasts.

Figure 18 With an endothermic reaction, the reactants have a lower energy level than the products. The reactants must overcome the activation energy barrier in order to form new products.

Endothermic Reactions With an endothermic reaction, the chemical reaction will not take place unless energy is added. A constant source of energy must be added to keep the reaction going. The products have more stored energy than the reactants.

Figure 18 shows an energy diagram for the reaction of carbon dioxide (CO_2) and nitrogen monoxide (NO). With an endothermic reaction, the reactants have a lower energy level than the products. In order for the products to form, an input of energy is needed for the reactants to overcome the activation energy barrier.

Exergonic Reactions

You have seen many reactions that release energy. Chemical reactions that release energy are called exergonic (ek sur GAH nihk) reactions. In these reactions, less energy is required to break the original bonds than is released when new bonds are formed. As a result, some form of energy, such as light or heat, is given off by the reaction. The familiar glow from the reaction inside a glow stick, shown in **Figure 19**, is an example of an exergonic reaction, which produces visible light. In other reactions, however, energy is released as heat. This is the case with some heat packs that are used to treat muscle aches and other medical conditions. Another release of energy is used to power rockets, as shown in **Figure 20**.

Figure 19 Glow sticks contain three different chemicals—an ester and a dye in the outer section and hydrogen peroxide in a center glass tube. Bending the stick breaks the tube and mixes the three components. The energy released is in the form of visible light.

LAB DEMONSTRATION

Purpose to demonstrate an exothermic process

Materials supersaturated solution of sodium acetate, sodium acetate crystal

Preparation Make a saturated solution of sodium acetate. Leave excess crystals in the bottom of the flask. Heat and stir until

the crystals dissolve. Cool undisturbed to room temperature.

Procedure Drop an additional crystal of sodium acetate into the solution. Have students watch the solution and carefully feel the outside of the flask.

Expected Outcome The solution will crys-

tallize, and the flask will become hot.

Assessment

Why did the solution release heat? The amount of energy required to break the bonds in the solution is less than the energy released when new crystals formed. The excess energy is released as heat. L2

Figure 20

Rockets burn fuel to provide the thrust necessary to propel them upward. In 1926, engineer Robert Goddard used gasoline and liquid oxygen to propel the first ever liquid-fueled rocket. Although many people at the time ridiculed Goddard's space travel theories, his rockets eventually served as models for those that have gone to the Moon and beyond. A selection of rockets—including Goddard's—is shown here. The number below each craft indicates the amount of thrust—expressed in newtons (N)—produced during launch.

▶ **JUPITER C** This rocket launched the first United States satellite in 1958. It used a fuel called hydyne plus liquid oxygen.

▼ **GODDARD'S MODEL ROCKET** Although his first rocket rose only 12.6 m, Goddard successfully launched 35 rockets in his lifetime. The highest reached an altitude of 2.7 km.

◀ **SPACE SHUTTLE** The main engines produce enormous amounts of energy by combining liquid hydrogen and oxygen. Coupled with solid rocket boosters, they produce over 32.5 million newtons (N) of thrust to lift the system's 2 million kg off the ground.

▼ **LUNAR MODULE** Smaller rocket engines, like those used by the Lunar Module to leave the Moon, use hydrazine-peroxide fuels. The number shown below indicates the fixed thrust from one of the module's two engines; the other engine's thrust was adjustable.

400 N

369,350 N

32,500,000 N

15,920 N

SECTION 4 Reaction Rates and Energy 737

Visualizing Chemical Energy

Have students examine the pictures and read the captions. Then ask the following questions.

How much more thrust did the Jupiter C rocket produce than Goddard's rocket? $369,350 \text{ N} / 400 \text{ N} = 923.38$ times more thrust

Why does the space shuttle require so much thrust to launch it into orbit? **because it has so much mass**

Activity

Rocket Technology Have students research the development of rocket technology throughout history and prepare time line posters showing the major milestones in this technology. [L2]

LS Visual-Spatial P

Quick Demo

Model Rocket

Materials various tube materials such as straws, towel tubes, plastic tubing

Estimated Time 30 minutes

Procedure Make several small "rockets" and demonstrate the amount of force it takes to launch them. Rockets can be simple straws (small inside a large straw) propelled by your lungs or tube constructions launched by a hand pump. Relate to the class that to use a greater force to launch the rocket requires a heavier, sturdier rocket to withstand the force. Demonstrate different designs to aid the flight of the rocket. Explain that the design to fly is an important consideration inside Earth's atmosphere, but is inconsequential in space. [L2]

Differentiated Instruction

Visually Impaired If students cannot see the model rocket you demonstrated in the Quick Demo activity, organize the class into small groups and have each group make its own model rocket. Visually impaired students can work with others to accomplish the rocket design and they can provide the thrust for the craft.

Challenge Ask students to research new developments in rocket technology and the projected dates that the new technology will be used. Ask students to give short oral reports to the class describing what they learn. [L3]

Mini LAB

Purpose to observe evidence of a chemical reaction **L2** **ELL**

Visual Spatial

Materials water, test tube, copper(II) bromide

Safety Precautions Use the safety symbols list to explain the safety hazards, examples, and precautions as they apply to this lab. Approve safety forms before work begins.

Teaching Strategies The chemical reaction that occurs is

Analysis

1. brown
2. blue
3. A chemical reaction occurred.

Assessment

Performance Have students repeat the activity and look for signs of energy absorbed or released by the reaction. Use **Performance Assessment in the Science Classroom**, p. 97.

Reading Check

Answer The energy given off by the reaction is primarily in the form of heat.

Mini LAB

Creating a Colorful Chemical Reaction

Procedure

1. Sprinkle a few crystals of **copper(II) bromide** into the **test tube**. Record the color of the crystals in your Science Journal.
2. Pour 5 mL of **water** into the test tube. Observe the color change of the crystals.
3. Slowly add more water and observe what happens.

Analysis

1. What color were the copper(II) bromide crystals after you added them to the test tube of water?
2. What color were they when you added more water?
3. What caused this color change?

Figure 21 In an exothermic reaction, molecules have enough energy to overcome the activation energy barrier. Energy is released with the formation of new products.

Exothermic Reactions When the energy given off in a reaction is primarily in the form of heat, the reaction is called an **exothermic reaction**. The burning of wood and the explosion of dynamite are exothermic reactions. Iron rusting is also exothermic, but, under typical conditions, the reaction proceeds so slowly that it's difficult to detect any temperature change.

Reading Check Why is a log fire considered to be an exothermic reaction?

Exothermic reactions provide most of the power used in homes and industries. Fossil fuels that contain carbon, such as coal, petroleum, and natural gas, combine with oxygen to yield carbon dioxide gas and energy. Unfortunately impurities in these fuels, such as sulfur, burn as well, producing pollutants such as sulfur dioxide. Sulfur dioxide combines with water in the atmosphere, producing acid rain.

Energy Release The energy diagram for an exothermic reaction is the reverse of an endothermic reaction. With an exothermic reaction, the products have less stored energy than the reactants. As shown in **Figure 21**, the reactants, carbon monoxide (CO) and nitrogen dioxide (NO₂) have a higher energy level than the products. The molecules have enough energy to overcome the activation energy barrier.

Chemical Reaction Rates

According to the kinetic theory of matter, atoms and molecules are always moving. In order for a chemical reaction to occur, the atoms and molecules that are the reactants have to bump into each other or collide. The **rate of reaction** is the speed at which reactants are consumed and products are produced in a given reaction.

Reaction rate is important in the manufacturing industry because the faster the product can be made, the less it usually costs. Sometimes a fast reaction rate is undesirable, such as the rate of reaction that causes food spoilage. In this case, the slower the reaction rate, the longer the food will stay edible. What conditions control the reaction rate, and how can the rate be changed?

Cultural Diversity

Japanese Chemistry In 1908, the Japanese chemist Kikunae Ikeda (1864–1936) used chemical reactions to make monosodium glutamate from hydrolyzed kelp protein. This synthesis became the foundation of Japan's chemical industry.

Reading Strategy

Discussion Groups Organize the class into groups of four students. Ask each group to discuss the following prompts: What role does energy play in chemical reactions? How are chemical reaction rates affected by different factors? Have students share a summary of their ideas with the class.

Real-World Rust

Purpose To recognize that some chemical reactions have financial impacts, explain to students that when metal rusts, money must be spent to correct the problem and prevent further corrosion.

Possible Materials pencil and paper

Estimated Time 20 minutes

Teaching Strategies

- Start the brainstorming by giving an example of corrosion on a bridge support. Visit each group to be sure they are thinking of appropriate examples.
- Do not limit the brainstorming to the problem and solutions of rust. Accept and discuss other types of chemical reactions that may have financial impacts.
- Accept and discuss chemical reactions that can have real-world impacts on health or safety and encourage creative solutions to these types of situations.

For additional inquiry activities, see *Science Inquiry Lab Manual*. L2

Discussion

Reaction Factors Explain to students that in order to react, molecules must collide, must have sufficient energy, and must collide with the correct orientation. Any factor, such as concentration, temperature, and catalysts that influence those requirements will have an effect on the reaction rate.

Teacher FYI

Determining Reaction Many reactions do not happen in a simple one-step process or mechanism. Two, three, or four more steps may be involved in the process that eventually converts the reactants to products. Each step may occur at a different rate.

Reaction Rate and Temperature

Figure 22 Increasing the temperature of a reaction increases the frequency of collisions, which will increase the rate of reaction.

Collisions are more frequent in a concentrated solution.

Collisions are less frequent in a dilute solution.

Figure 23 People are more likely to collide in crowds. Molecules behave similarly.

Post Reading

Extended Research Ask students to research the purpose of catalysts and inhibitors. Have them develop a short paper that describes the function of each, along with specific examples. Have students present their findings to the class.

Temperature Energy is needed by atoms and molecules to break old bonds and to form new ones. One way to increase the activation energy is to add heat or increase the temperature. With an increase in temperature, atoms and molecules move faster and kinetic energy increases. With faster moving atoms and molecules, more molecules have kinetic energy greater than activation energy. The atoms and molecules now will have enough energy to break old bonds at higher temperature, which will increase the reaction rate. A chemical reaction will go faster at higher temperature and slower at lower temperature as shown in **Figure 22**.

Concentration When you walk through the hallways at school, you are more likely to bump into another student if the hallways are crowded. A similar situation is shown in **Figure 23**. The closer atoms and molecules are to each other, the greater the chance of collision. The amount of substance present in a certain volume is called its concentration. Increasing the concentration of a substance increases the reaction rate.

Surface Area Only atoms or molecules in the outer layer of a substance can collide with other reactants. When a substance is finely divided, it has a larger surface area than when it was whole. Increasing the surface area increases the chance for collisions, which will increase the reaction rate. A powdered reactant will produce a faster reaction rate than a lump of the same reactant. For instance, grain elevator operators have to be careful of explosions and fire. The dust from the grains in the bin has a larger surface area than the whole grains. With an ignition spark, the dust will catch fire rapidly and cause an explosion.

Agitation If you are making lemonade, the water, sugar, and lemon juice are mixed in order to get the product. Agitation or stirring is a physical process that allows reactants to mix. A low stirring rate will slow the reaction due to fewer collisions. Chemical reactions can be controlled by agitation.

Pressure Another way to influence the reaction rate is with pressure. By increasing the pressure of gases, molecules have less room to move about and the concentration of the reactants increases. This will boost the chance of collisions, which means the reaction rate increases. Decreasing the pressure means fewer collisions, and lower reaction rate.

Catalysts The metals in exhaust catalysis help break down the unused hydrocarbon fuel molecules into less harmful compounds.

Research Have students research current trends in catalyst systems for automobiles and other vehicles that use fossil fuels. Findings can be noted in students' Science Journals.

✓ Reading Check

Answer lowers the activation energy

3 Assess

DAILY INTERVENTION

Check for Understanding

Sounds of Chemistry Reiterate that the boom sounds from fireworks are also the results of chemical reactions. Have students name other sounds of chemical reactions. *the backfire sound from a car or the pop sound from a toy cap gun* L2

Reteach

Chemical Energy Write the following two equations on the board:

Which equation depicts an endothermic reaction? *second one*
Which depicts an exothermic reaction? *first one* L2 LS **Logical-Mathematical**

✓ Assessment

Oral Ask students to suppose that they are each holding a test tube that has a chemical change taking place inside. The tube is beginning to feel colder. Is the process in the tube endothermic or exothermic? *Endothermic; the system is gaining energy from the surroundings—your hand.* Use PASC, p. 89. L2

Catalysts Metals, such as platinum and palladium, are used as catalysts in the exhaust systems of automobiles. What reactions do you think they catalyze?

Catalysts and Inhibitors Some reactions proceed too slowly to be useful. To speed them up, a catalyst reaction can be added. A **catalyst** is substance that speeds up a chemical reaction without being permanently changed itself. When you add a catalyst to a reaction, the mass of the product that is formed remains the same, but it will form more rapidly. A catalyst lowers the activation energy of the reaction. With the lowering of the activation energy, collisions among molecules now will become more effective, thus increasing the rate of reaction.

✓ **Reading Check** Explain how a catalyst speeds up a reaction.

At times, it is worthwhile to prevent certain reaction from occurring. Substances that are used to slow down a chemical reaction are called **inhibitors**. The food preservations BHT and BHA are inhibitors that prevent spoilage of certain foods, such as cereals and crackers.

One thing to remember when thinking about catalysts and inhibitors is that they do not change the amount of product produced. They only change the rate of production. Catalysts increase the rate and inhibitors decrease the rate. Other factors, including concentration, pressure, and temperature, also affect the rate of reaction and must be considered when catalyzing or inhibiting a reaction.

section 4 review

Summary

Conservation of Energy

- In a chemical reaction, the total amount of energy is the same. Energy is neither created nor destroyed.

Chemical Reactions and Energy

- Chemical reactions release or absorb energy, as chemical bonds are broken and formed.
- An endothermic reaction absorbs heat.
- An exothermic reaction releases heat.

Chemical Reaction Rates

- Temperature, concentration, and pressure can affect reaction rates.
- In an exothermic reaction, reactants have more energy than the products.
- In an endothermic reaction, the reactants have less energy than the products.

Self Check

1. **Explain** whether the term *endothermic* can be used to describe physical changes.
2. **Describe** how temperature can affect reaction rate.
3. **Illustrate** As an exothermic reaction, methane and oxygen will react to form carbon dioxide and water. Draw the activation energy chart showing where the reactants and products belong.
4. **Explain** why crackers containing BHT stay fresh longer than those without it.
5. **Think Critically** To develop a product that warms people's hands, would you choose an exothermic or endothermic reaction to use? Why?

Applying Math

6. **Calculate** If an endothermic reaction begins at 26°C and loses 2°C per minute, how long will it take to reach 0°C?
7. **Use Graphs** Create a graph of the data in question 6. After 5 min, what is the temperature of the reaction?

section 4 review

1. Endothermic can be used to describe physical changes.
2. A chemical reaction will go faster at a higher temperature and slower at a lower temperature.
3. The student's graph should be similar to Figure 21.
4. BHT slows the spoilage of the cracker.
5. Exothermic; it would release energy to warm people's hands.
6. 13 min
7. Check students' graphs. After 5 min, reaction is approximately 18°C.

MA.B.1.4.2, MA.E.1.4.1

CATALYZED Reaction

A balanced chemical equation tells nothing about the rate of a reaction. One way to affect the rate is to use a catalyst.

Real-World Problem

How does the presence of a catalyst affect the rate of a chemical reaction?

Goals

- Observe** the effect of a catalyst on the rate of reaction.
- Conclude**, based on your observations, whether the catalyst remained unchanged.

Possible Materials

test tubes (3)	hot plate
test-tube rack	wooden splint
3% hydrogen peroxide, H_2O_2 (15 mL)	beaker of hot water
10-mL graduated cylinder	manganese dioxide, MnO_2
small plastic teaspoon	(1 g)
sand (1 g)	

Safety Precautions

WARNING: Hydrogen peroxide and manganese dioxide can irritate skin and eyes. Point test tubes away from other students.

Procedure

- Label three test tubes and set them in a test-tube stand. Pour 5 mL of hydrogen peroxide into each tube.
- Place about 1 g of sand in tube 2 and the same amount of MnO_2 in tube 3.
- In the presence of a catalyst, H_2O_2 decomposes rapidly producing oxygen gas, O_2 .

Hypothesize what will happen when the smoldering wood is introduced to each test tube. Test each tube by lighting a wooden splint, blowing out the flame, and inserting the glowing splint into the tube. The splint will relight if oxygen is present.

- Place all three tubes in a beaker of hot water. Heat on a hot plate until all of the remaining H_2O_2 is driven away and no liquid remains.

Conclude and Apply

- Observe** the changes that happened when the solids were added to the tubes.
- Infer** which substance, sand or MnO_2 , was the catalyst.
- Identify** what remained in each tube after the H_2O_2 was driven away.

Communicating Your Data

Compare your results with those of your classmates and discuss any differences observed. For more help refer to the **Science Skill Handbook**.

Real-World Problem

Purpose Students operationally define a catalyst and observe its action. **L2** **KS** **Kinesthetic**

Process Skills observe, infer, form operational definitions, classify, recognize cause and effect

Time Required 30 minutes

Procedure

Safety Precautions Have students tie back long hair and keep clothing away from open flame. Use the safety symbols list to explain the safety hazards, examples, and precautions as they apply to this lab. Approve safety forms before work begins.

Teaching Strategy Demonstrate the glowing splint test for students.

Troubleshooting To ensure that the splint will relight, be sure the splints still have some glowing ember when introduced into the test tube. A completely cold splint will not relight.

Conclude and Apply

- There was no observable change from the addition of sand, but the MnO_2 increased the rate of oxygen production.
- manganese dioxide
- the sand in one tube, the MnO_2 in the other tube

Assessment

Performance Have students repeat the test with a small piece of liver instead of MnO_2 . Ask what was in the liver to cause increased O_2 production. **an enzyme** Use **Performance Assessment in the Science Classroom**, p. 97.

Communicating Your Data

Have students draw illustrations showing each test tube at each step of the procedure.

Real-World Problem

Purpose Explain and infer the factors of concentration, temperature, pressure, and catalyst that affect the rate of a chemical reaction.

Time Required 1 class period

Process Skills Analyze results, collect data, explain, infer, interpret data, observe, organize data, summarize, use scientific explanations

Procedure

Alternate Materials You can use small Erlenmeyer flasks instead of plastic water bottles. You can collect gases by water displacement to get more quantitative data.

Safety Precautions Use the safety symbols list to explain the safety hazards, examples, and precautions as they apply to this lab. Approve safety forms before work begins.

Follow Your Plan

Teaching Strategy You may want to demo the technique of setting up the balloons so students can see how it works.

Goals

- **Evaluate** the effect of concentration on the rate of a chemical reaction.
- **Examine** the effect of temperature on the rate of a chemical reaction.

Materials

water
vinegar solution
baking soda
balloons (3)
plastic 0.5-liter soft-drink bottles (3)
test tube
150-mL beakers (3)
100-mL graduated cylinder
marker
tape measure
stop watch
**clock with second hand*
**Alternate material*

Safety Precautions

Investigating Reaction Conditions

Real-World Problem

Many people believe that you cannot perform chemical reactions without expensive equipment or costly chemicals. But this isn't true; chemical reactions happen everywhere. All you need is a food store to find many substances that can produce exciting chemical reactions. What factors determine how much product is produced in a chemical reaction or how fast a reaction occurs?

Procedure

1. Copy the data tables into your Science Journal.
2. Prepare the following solutions: a 50% vinegar solution by mixing 50 mL of vinegar with 50 mL of water; a 30% vinegar solution by mixing 30 mL vinegar with 70 mL of water and a 10% vinegar solution by mixing 10 mL of vinegar with 90 mL of water. Pour these solutions into labeled 0.5-L plastic bottles.
3. Mark a small test tube about 1–2 cm from its bottom. Fill the test tube to the line with baking soda. Put the baking soda into one balloon. Repeat, adding baking soda to the other two balloons.

742 CHAPTER 23

Alternative Inquiry Lab

Real-World Connection To extend this lab, have students design an experiment that can collect quantitative results that can be graphed. Other reactions that can be carried out are the reaction of zinc with hydrochloric acid.

Using Scientific Methods

- Place the mouth of one balloon over the mouth of one 0.5-L bottle. Do not let any of the baking soda fall into the solution.
- Lift each balloon to allow the baking soda to fall into each vinegar solution. Observe time of reaction and measure how much each balloon inflates. Record your observations in your data table.
- Rinse the plastic bottles with water. Prepare three 30% vinegar solutions. Bottle A will have cold water added. Bottle B will have room temperature water added. Bottle C will have hot water added.
- Prepare the baking soda in the balloons as in step 3. Add the baking soda to the solution. Time how long it takes for the reaction to finish. Measure how much each balloon inflates. Record your observations in the data table.

Concentration Table

Concentration	50%	30%	10%
Observations	Do not write in this book.		

Temperature Table

Temperature	Cold Temp	Room Temp	Hot Temp
Observations	Do not write in this book.		

Analyze Your Data

- Describe** how increasing the concentration of a solution affects the rate of a chemical reaction.
- Summarize** how temperature affects the rate of a chemical reaction.
- Explain** why the balloons became inflated.

Conclude and Apply

- Infer** how a change in pressure can affect the rate of chemical reaction of this system.
- Explain** how temperature and balloon inflation are related.

Communicating Your Data

Compare your results with other students in your class.

LAB 743

Analyze Your Data

- The higher the concentration, the faster the rate of reaction.
- The higher the temperature, the faster the rate of reaction.
- The balloon became inflated because of the gas generated.

Conclude and Apply

- Increasing the pressure has the same effect as increasing the concentration, so the rate of reaction will increase.
- The higher the temperature, the more inflated the balloon became.

Assessment

Performance Design an experiment that quantitatively demonstrates how concentration or temperature affects the rate of chemical reaction. Use PASC, p. 95.

Test Your Model

Concentration	50 %	30 %	10 %
Observations	Balloon is biggest	Balloon is blown up	Balloon is smallest
Temperature	Cold	Room Temperature	Hot
Observations	very slow	medium rate	very fast

Communicating Your Data

Facilitate student discussion of results.

Content Background

When Chardonnet made his discovery in 1878, the French silk industry was in danger because something was causing the silkworms to die. Louis Pasteur was working to solve the mystery while, at the same time, Chardonnet was working to find a replacement for natural silk. He derived the solution from which he finally produced his artificial silk from the pulp of mulberry leaves, the natural food of silkworms. When he displayed the product at the Paris Exposition in 1889, he got backing for it immediately. It wasn't called rayon until about 1924.

Discussion

Learn from Mistakes Ask students why it might have been obvious to Chardonnet that his accident might lead to artificial silk. **because he had been searching for an artificial silk anyway** Discuss how this outcome might give students a new perspective on making mistakes. Remind students that we learn from mistakes and mistakes can often give a whole new outlook on a problem. [L2]

Analyze the Event

Eventually, the diseases striking silkworms were identified and controlled. Why do you think Chardonnet's artificial silk remained so popular? **Possible answers:** because now the amount of silk produced could be easily controlled. As much or as little fabric could be made as was necessary to meet demand. No longer did people have to worry about silkworms getting sick. [L2]

A Clumsy Move Pays Off

Great scientific discoveries can happen in some very unlikely ways. Most people might not think that an accidental spill left uncleaned would become significant, but that's exactly what led a chemist named Hilaire de Chardonnet (hee LAYR • duh • shar doh NAY) to his discovery. In 1878, Chardonnet accidentally knocked over some nitrate chemicals. He put off cleaning up the mess and ended up inventing artificial silk.

Silk is produced naturally by silkworms. In the mid-1800s, though, silkworms were dying from disease and the silk industry was suffering. Businesses were going under and people were put out of work. Many scientists were working to develop a solution to this problem. Chardonnet had been searching for a silk substitute for years—he just didn't plan to find it by knocking it over!

Hilaire de Chardonnet

A Messy Discovery

Chardonnet was in his darkroom developing photographs when the accidental spill took place. He decided to clean up the spill later and finish what he was working on. By the time he returned to wipe up the spill, the chemical solution had turned into a thick, gooey mess. When he pulled the cleaning cloth away, the goop formed long, thin strands of fiber that stuck to the cloth. The chemicals had reacted with the cellulose in the wooden table and liquefied it. The strands of fiber looked just like the raw silk made by silkworms.

Within six years, Chardonnet had developed a way to make the fibers into an artificial silk. Other scientists extended his work, developing a fiber called rayon. Today's rayon is made from sodium hydroxide mixed with wood fibers, which is then stranded and woven into cloth.

Rayon has another real-world application. To help prevent counterfeiting, dollars are printed on paper that contains red and blue rayon fibers. If you can scratch off the red or blue, that means it's ink and your bill is counterfeit. If you can pick out the red or blue fiber with a needle, it's a real bill.

Rayon fiber

Create Work with a partner to examine the fabric content labels on the inside collars of your clothes. Research the materials, then make a data table that identifies their characteristics.

For more information, visit fl.gpscience.com

Create Suggest students include in their tables information on the weather conditions for which each piece of clothing is used. Ask students to examine the textures and elasticity of the clothing and hypothesize how the polymers must be arranged. [L2]

Resources for Teachers and Students

Mistakes that Worked, by Charlotte Foltz Jones, Doubleday, 1994

They All Laughted . . . From Light Bulbs to Lasers, by Ira Flatlow, Perennial, 1993

Bright Ideas, by Sharon Dalglish, Mason Crest Publishers, 2003

Reviewing Main Ideas

Section 1 Chemical Changes

1. In a chemical reaction, one or more substances are changed to new substances.
2. The substances that react are called reactants, and the new substances formed are called products. Charcoal, the reactant shown below, is almost pure carbon.

3. The law of conservation of mass states that in chemical reactions, matter is neither created nor destroyed, just rearranged.
4. The law of conservation of energy states that energy is neither created nor destroyed.

Section 2 Chemical Equations

1. Balanced chemical equations give the exact number of atoms involved in the reaction.
2. A balanced chemical equation has the same number of atoms of each element on both sides of the equation. This satisfies the law of conservation of mass.
3. When balancing chemical equations, change only the coefficients of the formulas, never the subscripts. To change a subscript would change the compound.

Section 3 Classifying Chemical Reactions

1. In synthesis reactions, two or more substances combine to form another substance.
2. In single-displacement reactions, one element replaces another in a compound.
3. In double-displacement reactions, ions in two compounds switch places, often forming a gas or insoluble compound.
4. Using the activity series chart, scientists can determine which metal can replace another metal.

Section 4 Reaction Rates and Energy

1. When energy is released in the form of heat, the reaction is exothermic. An endothermic reaction requires heat to get started. This flame is releasing light and heat energy.
2. Temperature, concentration, and the presence of a catalyst can change the rate of reaction.
3. Activation energy is the minimum amount of energy needed to start a reaction.
4. Reactions may be sped up by adding catalysts, such as a nickel catalyst. A reaction can be slowed down by adding inhibitors.

FOLDABLES Use the Foldable that you made at the beginning of this chapter to help you review chemical reactions.

Reviewing Main Ideas

Summary statements can be used by students to review the major concepts of the chapter.

Assessment Transparency

For additional assessment questions, use the *Assessment Transparency* located in the transparency book.

Assessment

Assessment Transparency Chapter **23**

Directions: Carefully review the diagrams and answer the following questions.

1. From the results of the experiment above, it is reasonable to assume that the production of ethene

- A has no effect on the rotting of a peach in its immediate area
- B slows the rotting of a peach in its immediate area
- C quickens the rotting of a peach in its immediate area
- D slows the rotting process in the peach producing the gas

2. According to the information in the diagram, we can conclude that ethene consists of

- F hydrogen and helium
- G carbon and hydrogen
- H carbon and oxygen
- J calcium and carbon

3. George wanted to use the peaches that he picked from the tree in his backyard to bake a pie. However, some were not quite ripe. George could best speed the ripening process by placing the peaches

- A in the refrigerator
- B outside by the tree
- C inside an enclosed space
- D near a breezy window

L2

FOLDABLES Have students use the Foldables that they made at the beginning of the chapter to help them review scientific processes.

Using Vocabulary

- The two are opposite processes; in a synthesis reaction substances are put together and in a decomposition reaction they are taken apart.
- In a chemical change, reactants change into products.
- The two produce opposite outcomes; catalysts speed up chemical reactions, while inhibitors slow them down.
- The two are opposite reactions; exothermic reactions release heat and endothermic reactions absorb heat.
- Chemical reactions are processes in which new substances, called products, are formed.
- In single-displacement reactions, only one element of one compound is replaced by another element. In double-displacement reactions, two elements in two compounds change places.
- Not all chemical reactions are synthesis reactions, but all synthesis reactions are chemical reactions.

Checking Concepts

- | | |
|-------|-------|
| 8. D | 13. D |
| 9. D | 14. B |
| 10. D | 15. A |
| 11. D | 16. D |
| 12. C | 17. D |

SC.B.1.4.1, SC.B.1.4.2

Using Vocabulary

- | | |
|-------------------------------------|---------------------------------|
| activation energy p. 735 | endothermic reaction p. 731 |
| balanced chemical equation p. 726 | exothermic reaction p. 731 |
| catalyst p. 740 | inhibitor p. 740 |
| chemical equation p. 723 | product p. |
| chemical reaction p. 720 | rate of reaction p. |
| combustion reaction p. 730 | reactant p. |
| decomposition reaction p. 731 | single-displacement reaction p. |
| double-displacement reaction p. 732 | synthesis reaction p. 7 |

F CAT Vocabulary

For each set of vocabulary words below, explain the relationship that exists.

- synthesis reaction—decomposition reaction
- reactant—product
- catalyst—inhibitor
- exothermic reaction—endothermic reaction
- chemical reaction—product
- single-displacement reaction—double-displacement reaction
- chemical reaction—synthesis reaction

Checking Concepts

Choose the word or phrase that best answers the question.

- Oxygen gas is always written as O_2 in chemical equations. What term is used to describe the “2” in this formula?
A) catalyst C) product
B) coefficient D) subscript
- In an endothermic reaction, which has the lower energy?
A) catalyst C) product
B) inhibitor D) reactant
- What law is based on the experiments of Lavoisier?
A) atomic theory
B) collision theory
C) conservation of energy
D) conservation of mass
- What must an element be in order to replace another element in a compound?
A) less inhibiting C) more inhibiting
B) less reactive D) more reactive
- How do you indicate that a substance in an equation is a solid?
A) (l) C) (s)
B) (g) D) (aq)
- Classify the reaction:
 $2H_2(g) + O_2(g) \rightarrow 2H_2O(g)$.
A) combustion
B) decomposition
C) single displacement
D) synthesis
- What compound is the food additive BHA?
A) catalyst C) oxidized
B) inhibitor D) reduced
- Which symbol indicates that a substance is dissolved in water when writing an equation?
A) (aq) C) (g)
B) (s) D) (l)
- What word would you use to describe HgO in the reaction that Lavoisier used to show conservation of mass?
A) catalyst C) product
B) inhibitor D) reactant
- When hydrogen burns, what is oxygen's role?
A) catalyst C) product
B) inhibitor D) reactant

Use the ExamView® Pro Testmaker CD-ROM to:

- create multiple versions of tests
- create modified tests with one mouse click for inclusion students
- edit existing questions and add your own questions
- build tests aligned with state standards using built-in State Curriculum Tags
- change English tests to Spanish with one mouse click and vice versa

Interpreting Graphics

18. Copy and complete the concept map using the following terms: *oxidized*, *redox reactions*, *lost*, *reduced*, *oxidation*, *gained*, and *reduction*.

19. **Sequence** Sometimes a bond formed in a chemical reaction is weak and the product breaks apart as it forms. This is shown by a double arrow in chemical equations. Copy and complete the concept map, using the words *product(s)* and *reactant(s)*. In the blank in the center, fill in the formulas for the substances appearing in the reversible reaction.

Thinking Critically

20. Write a balanced chemical equation for the reaction of propane $\text{C}_3\text{H}_8(\text{g})$ burning in oxygen to form carbon dioxide and water vapor.
21. Interpret the balanced chemical equation from question 23 to explain the law of conservation of mass.
22. **Hypothesize** Zn is placed in a solution of $\text{Cu}(\text{NO}_3)_2$ and Cu is placed in a $\text{Zn}(\text{NO}_3)_2$ solution. In which of these will a reaction occur?
23. **Predict** what kind of energy process happens when lye, $\text{NaOH}(\text{s})$, is put in water and the water gets hot.
24. **Recognize Cause and Effect** Sucrose, or table sugar, is a disaccharide. This means that sucrose is composed of two simple sugars chemically bonded together. Sucrose can be separated into its components by heating it in an aqueous sulfuric acid solution. Research what products are formed by breaking up sucrose. What role does the acid play?
25. **Classify** Make an outline with the general heading *Chemical Reactions*. Include the five types of reactions, with a description and example of each.

Applying Math

26. **Use Numbers** When 46 g of sodium were exposed to dry air, 62 g of sodium oxide formed. How many grams of oxygen from the air were used?
27. **Calculate Mass** Chromium is produced by reacting its oxide with aluminum. If 76 g of Cr_2O_3 and 27 g of Al completely react to form 51 g of Al_2O_3 , how many grams of Cr are formed?

Interpreting Graphics

18. See student page.
19. See student page.

Thinking Critically

20. $\text{C}_3\text{H}_8(\text{g}) + 5\text{O}_2(\text{g}) \rightarrow 3\text{CO}_2(\text{g}) + 4\text{H}_2\text{O}(\text{g})$
21. There are 3 atoms of carbon, 8 atoms of hydrogen, and 10 atoms of oxygen on both sides of the equation.
22. Zinc reacts in the solution of copper nitrate and displaces copper to form $\text{Zn}(\text{NO}_3)_2$. In the second solution, no reaction is observed.
23. exothermic
24. Fructose and glucose; the acid is a catalyst.
25. Chemical Reactions
- Combustion Reaction**
A substance reacts with oxygen to produce energy as heat or light.
 - Synthesis Reaction**
Two or more elements or compounds combine.
 - Decomposition**
A compound is broken down into its elements or other compounds.
 - Single Displacement**
An element in one compound is replaced by another element.
 - Double Displacement**
Two elements from two different compounds replace each other. Accept all reasonable examples.

Applying Math

Math Standards

National: 1, 2, 9, 10

Florida: MA.D.2.4.1

26. $62 \text{ g} - 46 \text{ g} = 16 \text{ g of O}_2$
27. 52 g

SC.B.1.4.1

Multiple Choice

Use the illustration below to answer question 1.

SC.B.1.4.2

1. The photograph above shows a chemical reaction in which water decomposes into hydrogen gas and oxygen gas when an electric current is passed through it. Which of the following is the correct chemical equation for this reaction?

- A. $\text{H}_2\text{O}(l) \rightarrow \text{H}_2(g) + \text{O}(g)$
- B. $\text{H}_2\text{O}(l) \rightarrow 2\text{H}(g) + \text{O}(g)$
- C. $2\text{H}_2\text{O}(l) \rightarrow 2\text{H}_2(g) + 2\text{O}(g)$
- D. $2\text{H}_2\text{O}(l) \rightarrow 2\text{H}_2(g) + \text{O}_2(g)$

2. Which substance is the precipitate in the following reaction?

- A. $\text{Ba}(\text{NO}_3)_2$
- B. K_2SO_4
- C. BaSO_4
- D. KNO_3

3. Which reaction is endothermic?

- A. iron rusting
- B. burning wood
- C. exploding dynamite
- D. mixing Epsom salt in water

Use the figure below to answer question 4.

4. Which metal would most likely replace lead in a solution?

- A. potassium
- B. copper
- C. silver
- D. gold

5. Which type of reaction is the opposite of a synthesis reaction?

- A. displacement
- B. reversible
- C. combustion
- D. decomposition

Gridded Response

SC.8.14.2

6. A reaction of 24 g of sodium hydroxide with 20 g of hydrogen chloride gives off 12 g of water. What mass of sodium chloride is formed in this reaction?

SC.8.14.2

7. From an experiment to separate water into hydrogen and oxygen, a student collected 10.0 g of hydrogen and 79.4 g of oxygen. How much water was originally involved in the process?

Short Response

8. What is a synthesis reaction?

Use the illustration to answer question 9.

SC.8.14.2

9. The illustration above shows the reaction of aqueous nickel(II) chloride, NiCl_2 , and aqueous sodium hydroxide, NaOH , to form solid nickel(II) hydroxide, $\text{Ni}(\text{OH})_2$, and aqueous sodium chloride, NaCl . State the conservation of mass as it applies to this chemical reaction.

10. Food preservatives are a type of inhibitor. Explain why this is useful in foods.

Extended Response

11. Explain what is wrong with the following balanced equation:

What is the correct form of the equation?

Use the illustration to answer question 12.

SC.8.14.1

12. The photograph above shows a chemical reaction between magnesium, Mg , and oxygen gas, O_2 . This reaction is exergonic and exothermic. Explain what these terms mean and how you can tell that a chemical reaction is exergonic or exothermic.

SC.8.14.2

13. The reaction of magnesium and oxygen gas forms magnesium oxide, MgO . Write the chemical equation for this reaction and explain the process you use to balance the equation.

Test-Taking Tip

Missing Information Questions often will ask about missing information. Notice what is missing as well as what is given.

Extended Response

11. The equation has oxygen as a single atom; however, oxygen gas is a diatomic molecule, O_2 . The correct form of the equation is $4\text{Al}(s) + 3\text{O}_2(g) \rightarrow 2\text{Al}_2\text{O}_3(s)$.
12. A chemical reaction is exergonic if it releases energy. A reaction is exothermic if it gives off energy in the form of heat. The reaction shown is exergonic because it releases heat and produces visible light. It is exothermic because it produces warmth and burning.
13. The unbalanced chemical equation is $\text{Mg}(s) + \text{O}_2(g) \rightarrow \text{MgO}(s)$. To balance the equation, adjust the coefficient with MgO to balance oxygen and with Mg to balance magnesium. The equation is balanced as $2\text{Mg}(s) + \text{O}_2(g) \rightarrow 2\text{MgO}(s)$.

Rubrics

For more help evaluating Short- and Extended-Response questions, see the rubrics on p. 9T.

Short Response

8. A synthesis reaction is a chemical reaction in which two or more substances combine to form another substance.
9. The number of atoms of nickel, chlorine, sodium, oxygen, and hydrogen that are present before the reaction equals the number of each present after the reaction.
10. An inhibitor slows down the rate of a reaction. Preservatives slow down the rate of food spoilage.

Section/Objectives	Standards		Labs/Features
	National	State/Local	
Chapter Opener	See pp. 16T–17T for a Key to Standards.		Launch Lab: Magic Solutions, p. 751 Foldables, p. 751
Section 1 How Solutions Form  2 sessions  1 block 1. Identify the components of a solution. 2. Explain how things dissolve. 3. Identify the factors that affect the rates at which solids and gases dissolve in liquids.	National Content Standards: UCP.1–3, UCP.5, A.1, A.2, B.1, B.2, B.3	Florida Benchmarks: SC.A.1.4	Integrate Career, p. 753 Visualizing Metal Alloys, p. 754 MiniLAB: Observing the Effect of Surface Area, p. 756  Video Lab Applying Math: Surface Area, p. 757
Section 2 Solubility and Concentration  1 session  .5 block 4. Define the concept of solubility. 5. Identify how to express the concentration of solutions. 6. List and define three types of solutions. 7. Describe the effects of pressure and temperature on the solubility of gases.	National Content Standards: UCP.1–3, UCP.5, A.1, A.2, B.2, B.6	Florida Benchmarks: SC.A.1.4.4	Science Online, p. 762
Section 3 Acids, Bases, and Salts  3 sessions  1.5 blocks 8. Compare and contrast acids and bases and identify the characteristics they have. 9. Examine some formulas and uses of common acids and bases. 10. Determine how the processes of ionization and dissociation apply to acids and bases.	National Content Standards: UCP.1, UCP.2, UCP.3, UCP.5, A.1, A.2, B.2, B.3	Florida Benchmarks: SC.A.1.4.2	MiniLAB: Observing Acid Relief, p. 766 Integrate Life Science, p. 768 Science Online, p. 770
Section 4 Strength of Acids and Bases  2 sessions  1 block 11. Determine what is responsible for the strength of an acid or a base. 12. Compare and contrast strength and concentration. 13. Examine the relationship between pH and acid or base strength. 14. Explain electrical conductivity.	National Content Standards: UCP.1, UCP.2, UCP.3, UCP.5, A.1, A.2, B.2, B.3		Lab: Determining Acidity, p. 775 Lab: Saturated Solutions, pp. 776–777

Section Focus

Section Focus Transparency **Your Lunchtime Solution**

The situation you face in chemistry may be a mystery. There are different kinds of mixtures, some are the same throughout while others are mixed unevenly. This picture shows a few of both kinds of mixtures.

Which of these mixtures are the same throughout? Which are mixed unevenly? Do you think the salad is the same kind of mixture as the vinegar? Why? What mixtures do you depend on every day?

L2

Section Focus Transparency **Situation Critical**

While we need some many substances it doesn't always work. When you take your bath you often change the bathwater. Bathwater is changed with sodium hydroxide (NaOH) which is a strong base. It is used once being developed that is less toxic than sodium hydroxide. The process is shown here.

What kinds of substances will not come off in water alone? How do detergents help clean things?

L2

Section Focus Transparency **A Sweet Job**

Sapwood of some maple trees in the northeastern states and Canada is used to make maple syrup. Sap is taken from the maple tree in a hollowed-out hole. It is then processed however this water solution is concentrated. It is then taken out in gallons of sap to produce one gallon of maple syrup.

What kind of mixture is the sapwood? What kind of mixture is the maple syrup? What kind of mixture is the concentrated maple syrup?

L2

This is a representation of key blackline masters available in the Teacher Classroom Resources. See Resource Manager boxes within the chapter for additional information.

Key to Teaching Strategies

The following designations will help you decide which activities are appropriate for your students.

- L1** Level 1 activities should be appropriate for students with learning difficulties.
- L2** Level 2 activities should be within the ability range of all students.
- L3** Level 3 activities are designed for above-average students.
- ELL** ELL activities should be within the ability range of English Language Learners.

COOP LEARN Cooperative Learning activities are designed for small group work.

MS Multiple Learning Styles logos, as described on page 12T, are used throughout to indicate strategies that address different learning styles.

P These strategies represent student products that can be placed into a best-work portfolio.

PBL Problem-Based Learning activities apply real-world situations to learning.

Assessment

Assessment Transparency **Solutions**

Directions: Fill in the table.

Composition of Common Solutions	
Solution	Created by combining
Brass	Solid-solid
Salt water	Solid-liquid
Vinegar	Liquid-liquid
Soda	Gas-liquid
Air	Gas-gas

1. According to the information in the table:
- A. solutions are always liquid in form
 - B. solutions are always gases
 - C. solutions are always liquid or gases
 - D. solutions can be solid, liquid or gas
2. According to the table, vinegar is created by combining:
- A. liquids
 - B. solids
 - C. solids with gases
 - D. liquids with gases
3. For the examples in the table, the solutions consisting of a liquid combined with either a gas or a solid are:
- A. solids
 - B. liquids
 - C. gases
 - D. water

How Solutions Form**How Substances Dissolve**

Attractive forces between the atoms, ions, or molecules of a substance hold liquid and solid substances together. When a substance is surrounded by a solvent, particles of the substance may be attracted to the solvent molecules by various forces. If these attractive forces are strong enough to overcome the internal attractive forces of the solute, the substance will be soluble to some extent. A substance with an extremely low solubility is usually said to be insoluble.

The process of dissolving, called dissolution, involves energy. Energy is absorbed when the structure of a molecular solid or liquid is broken down or the ions of an ionic crystal are separated. Energy is released when the particles of solute form new bonds with the solvent. In the cold packs used by athletic trainers, more energy is absorbed in the first part of the dissolution process than is released in the second. For that reason, the overall process is endothermic, and the liquid becomes colder.

David R. Frazier/ Photo Researchers, Inc.

section

2

Solubility**and Concentration****Types of Solutions**

A solution is saturated when equilibrium between the undissolved solute and dissolved solute is established at a particular temperature. It is important to state the temperature of a saturated solution. Because a solution that is saturated at one temperature may not be saturated at another temperature. In the state known as solution equilibrium, the solute is dissolving into the solution and coming out of solution at exactly the same rate.

If a solution contains more dissolved solute than it usually can hold at a given temperature, the solution is said to be supersaturated. Supersaturated solutions are unstable and disturbances such as jarring, stirring, scratching the walls of the container, or dropping in a “seed” crystal cause the solution to return to the saturated state.

section

3

Acids, Bases, and Salts**Solutions of Acids and Bases**

A good operational definition of acids and bases is that acids increase the concentration of hydronium ions (H_3O^+) when dissolved in water and bases increase the concentration of hydroxide ions when dissolved in water. Other characteristics come from work by Robert Boyle in the 1600s. Acids have a sour taste, are corrosive, turn litmus from blue to red, and lose their acidity when they react with alkaline (basic) materials. Bases feel slippery, change litmus from red to blue, and become less *alkaline* when they react with acids. The word alkaline became synonymous with basic because alkalines are the “basis” for making salts.

Strength of Acids and Bases pH of a Solution

The term pH is derived from the German *potenz* (power) and H for hydrogen. It refers to the power of 10 used to express the molar H_3O^+ concentration. The approximate pH of a solution can be determined by using an acid-base indicator. Bromothymol blue, for instance, changes color in the pH range 6.0–7.6 from yellow in its acid form to blue in its base form. Phenolphthalein changes in the pH range of 8.2–9.8 from colorless in its acid form to pink in its base form. A mixture of indicators called universal indicator can be used that measures the range of pH from 0–14.

A salt is an ionic compound that is formed when an acid neutralizes a base. Salt solutions can be neutral, acidic, or basic, depending on the acid-base properties of the constituents. As a general rule, salts formed by the reaction of a strong acid with a strong base are neutral, salts formed by reaction of a strong acid with a weak base are acidic, and salts formed by the reaction of a weak acid with a strong base are basic.

Teacher to Teacher

Pam K. Hintz,
Elgin/New Leipzig Public School
Elgin, North Dakota

"To show how solutions can be useful in analytical applications, I prepare a simple chromatography demonstration. I place a dot of permanent marker near the bottom of a strip of coffee filter paper and a dot of water-based marker ink on another strip. Then I dip the strips in separate beakers with a small amount of water (water line below the ink dots) and let them sit for about 45 minutes. We take a minute for the students to predict what will happen and we come back to the beakers at the end of class. Students should see that the water-based ink dissolved in the water and, as the water was absorbed up the paper, separated out to show the colors that combined to make the ink. Chromatography techniques like this one are used to isolate and analyze the individual components of unknown substances."

Pam K. Hintz

Mixed-Up Chemistry

This diver is swimming in a solution. Seas are solutions that contain dissolved solids, such as calcium and magnesium, and dissolved gases, such as carbon dioxide, in water. In this chapter, you will learn about solutions, acids, and bases.

Science Journal Are all liquids solutions, and are all solutions liquids? Answer this question in your Science Journal. Check your answer later and revise it if you've learned differently.

750

Theme Connection

Systems and Interactions Solutions are systems whose properties are determined by the interactions between the molecules or ions of the solute and the molecules or ions of the solvent.

About the Photo

Underwater Solutes This diver may not know it, but the underwater environment is full of solutes in solution. Water dissolves many substances, and the salty seawater itself is a solution. The oxygen tank that makes this dive possible also contains a solution—a gas solution of nitrogen or possibly helium mixed with oxygen.

Start-Up Activities

Magic Solutions

To prevent spies from learning military secrets, scientists developed a special ink that is invisible on paper at room temperature. When the paper is warmed by a candle or lightbulb, the message appears. In this lab, you will create an invisible message.

1. Write a message or draw a picture on a white sheet of paper using a cotton swab dipped in either phenolphthalein indicator or universal indicator. In your Science Journal, record which indicator you used.
2. Allow the paper to dry thoroughly.
3. Dip a clean cotton ball in household ammonia (a base) or vinegar (an acid) and rub it across your paper. Record which solution you used and your observations in your Science Journal.
4. Compare your results with those of others.
5. **Think Critically** In your Science Journal, infer how the magic solution works.

FOLDABLES™ Study Organizer

Solutions, Acids, and Bases
Make the following Foldable to help you identify the main characteristics of solutions, acids, and bases.

- STEP 1** Fold a sheet of paper vertically from side to side. Make the front edge about 1.25 cm longer than the back edge.

- STEP 2** Turn lengthwise and fold into thirds.

- STEP 3** Unfold and cut only the top layer along both folds to make three tabs.

- STEP 4** Label each tab.

Reading for Main Ideas As you read the chapter, list the characteristics of solutions, acids, and bases.

Purpose Use the Launch Lab to introduce students to the concept of acids and bases. **L2** **LS**

Kinesthetic

Materials white paper, cotton balls, cotton swabs, phenolphthalein indicator, universal indicator, ammonia, vinegar

Teaching Strategy

To extend this activity, students could use vinegar and baking soda dissolved in water to write a message. The message is then revealed using red cabbage indicator. If acidic and basic solutions are used, the messages will show up as different colors.

Think Critically

Sample answer: The writing appeared when vinegar or ammonia was rubbed across an indicator. The pH changed, which allowed the writing to appear.

Assessment

Oral Ask students to explain how indicators can show if a solution is acidic or basic. The indicator will be one color for acids and another color for bases.

L2 ELL

Section Focus Transparency *Your Lunchtime Solution*

The solution to your lunchtime hunger may be a mixture. There are different kinds of mixtures—some are the same throughout, while others are mixed unevenly. This picture shows a few of both kinds of mixtures.

- Which items in this picture are the same throughout? Which are unevenly mixed?
- Do you think the salad is the same kind of mixture as the vinegar? Why?
- What invisible mixture do you depend on every moment of every day?

L2

Reading Preview

Tie to Prior Knowledge

Mixtures Have students recall what they know about heterogeneous and homogeneous mixtures. In a heterogeneous mixture, the mixed materials are not distributed evenly. A homogeneous mixture is one in which the particles are distributed evenly at the molecular or ionic level. L2

Word Analysis Point out that several words in this section are followed by syllables in parentheses. These syllables show how to pronounce the words correctly. Model the process with *aqueous* (A kwee us) *solu-tion*. Point out that *aqua* means “water” and is derived from Latin.

Reading Guide

FCAT Vocabulary

What You'll Learn

- **Identify** the components of a solution.
- **Explain** how things dissolve.
- **Identify** the factors that affect the rates at which solids and gases dissolve in liquids.

Why It's Important

Solutions play an important role in your everyday life. Examples of everyday solutions are sports drinks, dishwashing detergents, and shampoos.

Review Vocabulary

homogeneous mixture: solid, liquid, or gas that contains two or more substances blended evenly throughout

New Vocabulary

- solution
- solute
- solvent
- ★ **aqueous solution**

What is a solution?

Hummingbirds are fascinating creatures. They can hover for long periods while they sip nectar from flowers through their long beaks. To attract hummingbirds, many people use feeder bottles containing a red liquid, as shown in **Figure 1**. The liquid is a solution of sugar and red food coloring in water.

Suppose you are making some hummingbird food. When you add sugar to water and stir, the sugar crystals disappear. When you add a few drops of red food coloring and stir, the color spreads evenly throughout the sugar water. Why does this happen?

Hummingbird food is one of many solutions. A **solution** is a mixture that has the same composition, color, density, and even taste throughout. The reason you no longer see the sugar crystals and the reason the red dye spreads out evenly is that they have formed a completely homogeneous mixture. The sugar crystals broke up into sugar molecules, the red dye into its molecules, and both mixed evenly among the water molecules.

Solutes and Solvents

In a solution, one substance is dissolved in another. In the hummingbird solution, sugar which is the substance being dissolved, is the **solute**. Water, which is the substance doing the dissolving, is the **solvent**. When a solid dissolves in a liquid, the solid is the solute and the liquid is the solvent. In salt water, salt is the solute and water is the solvent. In carbonated soft drinks, carbon dioxide gas is one of the solutes and water is the solvent. When a liquid dissolves in another liquid, the substance present in the larger amount is usually called the solvent. A solution in which water is the solvent is called an **aqueous** (A kwee us) **solution**.

Reading Check How do you know which substance is the solute in a solution?

Nonliquid Solutions Solutions also can be gaseous or even solid. Examples are shown in **Figure 1** and **Figure 2**. Did you know that the air you breathe is a solution? In fact, all mixtures of gases are solutions. Air is a solution of 78 percent nitrogen, 21 percent oxygen, and small amounts of other gases such as argon, carbon dioxide, and hydrogen. The sterling silver and brass used in musical instruments are an example of a solid solution. The sterling silver contains 92.5 percent silver and 7.5 percent copper. The brass is a solution of copper and zinc metals. Solid solutions are known as alloys. They are made by melting the metal solute and solvent together. Most coins, as shown in **Figure 3**, are alloys.

Figure 2 Solutions also can be mixtures of solids or gases. **Identify** the parts of a solution.

SECTION 1 How Solutions Form 753

Surface-Coating Chemist

A scientist who develops products such as house paints and polyurethane wood finishers is called a surface-coating chemist. Paints, varnishes, and synthetic clear coatings are solutions. These products are designed to protect the surface of an object from the environment. Make a list of five items that have a protective coating that was applied as a solution.

2 Teach

Caption Answer

Figure 2 solute and solvent

Reading Check

Answer It is the substance being dissolved and is usually the substance that is present in the lesser amount.

Activity

Salt Residue Have students stir table salt into 50 mL of water until no more salt dissolves. Then have them add 5 mL of powdered chalk and stir again. Have them pour the liquid through filter paper. They should observe the chalk on the filter paper. Have them evaporate the filtered liquid and observe the residue remaining (salt). Explain that if filter paper can separate a substance out of a liquid, the substance was not dissolved. The chalk did not dissolve; the salt did. **L2 ELL**

Visual-Spatial

Surface-Coating Chemist Suggested answers: polyurethane on wood floors, parking lot line marks, house paint, and nail polish

These chemists usually have a degree in chemistry and specialize in surface coatings. Many colleges offer four-year degrees in chemistry, but fewer colleges offer courses in surface coatings.

Research Have students research to find colleges and universities that offer classes in surface coating.

Science Journal

Everyday Solvents and Solutes Have students recall that solvents and solutes are all around them. Ask them to list in their Science Journals solvents and solutes they encounter in their daily lives. **Their bodies contain solutes dissolved in water. Paint thinner, spot removers, and nail polish remover are all solvents that do not contain water.** **L2 L** **Linguistic**

Reading Strategy

Set the Purpose Have students outline this section using text headings as guides. Set the purpose by asking them to make sure their outlines contain main ideas. Remind them that main ideas are often signaled by words and phrases in bold.

Visualizing Metal Alloys

Have students examine the pictures and read the captions. Then ask the following questions.

Why is it necessary for vending machines to be able to recognize a coin by its size, weight, and electrical conductivity? All three properties are difficult to duplicate in counterfeit coins or slugs. It also compensates for the machine's lack of visual recognition.

Look at the photograph of the two types of dollars. Do they appear to be made from the same alloy? No, the Susan B. Anthony dollar appears to be made of a material, such as nickel or silver, that is silver in color. The Sacagawea dollar is copper in color, similar to the element copper.

Activity

Coin Composition Have students find the composition of the Susan B. Anthony dollar. Construct a circle graph for the Susan B. Anthony dollar similar to the one shown in the text for the Sacagawea dollar. [L2]

LS Logical-Mathematical

Figure 3

Have you ever accidentally put a non-United States coin into a vending machine? Of course, the vending machine didn't accept it. If a vending machine is that selective, how can it be fooled by two coins that look and feel very different? This is exactly the case with the silver Susan B. Anthony dollar and the new golden Sacagawea dollar. Vending machines can't tell them apart.

Susan B. Anthony dollar

Sacagawea dollar

◀ Vending machines recognize coins by size, weight, and electrical conductivity. The size and weight of the Susan B. Anthony coin were easy to copy. Copying the coin's electrical conductivity was more difficult.

▲ The dollar's copper core is half the coin's thickness. It is sandwiched between two layers of manganese brass alloy.

▲ Over 30,000 samples of coin coatings were tested to find an alloy and thickness that would copy the conductivity of the Susan B. Anthony dollar. The final composition of the alloy is shown in the graph above. The key ingredient? Manganese.

Differentiated Instruction

Challenge Have students find out how vending machines check the size, weight, and electrical conductivity of coins. Have students report their findings to their class. [L3] **LS** Linguistic

Teacher FYI

Alloys Steel is an alloy of mostly iron with various other metals and semimetals added. Chromium, carbon, and nickel are solutes added to molten iron, which is cooled to make a solid alloy.

How Substances Dissolve

Fruit drinks and sports drinks are examples of solutions made by dissolving solids in liquids. Like hummingbird food, both contain sugar as well as other substances that add color and flavor. How do solids such as sugar dissolve in water?

The dissolving of a solid in a liquid occurs at the surface of the solid. To understand how water solutions form, keep in mind two things you have learned about water. Like the particles of any substance, water molecules are constantly moving. Also, water molecules are polar, which means they have a positive area and a negative area. Molecules of sugar also are polar.

How It Happens Molecules of sugar dissolving in water are shown in **Figure 4**. First, water molecules cluster around sugar molecules with their negative ends attracted to the positive ends of the sugar. Then, the water molecules pull the sugar molecules into solution. Finally, the water molecules and the sugar molecules mix evenly, forming a solution.

Reading Check *How do water molecules help sugar molecules dissolve?*

The process described in **Figure 4** repeats as layer after layer of sugar molecules move away from the crystal, until all the molecules are evenly spread out. The same three steps occur for most solid solutes dissolving in a liquid solvent.

Dissolving Liquids and Gases The same process takes place when a gas dissolves in a liquid. Particles of liquids and gases move much more freely than do particles of solids. When gases dissolve in gases or when liquids dissolve in liquids, this movement spreads solutes evenly throughout the solvent, resulting in a homogenous solution.

Dissolving Solids in Solids How can you mix solids to make alloys? Although solid particles do move a little, this movement is not enough to spread them evenly throughout the mixture. The solid metals are first melted and then mixed together. In this liquid state, the metal atoms can spread out evenly and will remain mixed when cooled.

Figure 4 Dissolving sugar in water can be thought of as a three-step process.

Step 1 Moving water molecules cluster around the sugar molecules as their negative ends are attracted to the positive ends of the sugar molecules.

Step 2 Water molecules pull the sugar molecules into solution.

Step 3 Water molecules and sugar molecules spread out to form a homogeneous mixture.

Visual Learning

Figure 4 Place a box of foam spheres in the center of a group of students who have linked arms. Tell students that they are solvent particles and the spheres are solute particles. In order for a sphere to dissolve, it must be held by a student. Discuss the three dissolving steps presented on the page. Then have students act out the steps with the spheres as you call out Step 1, Step 2, and Step 3. The activity can also be used to discuss the advantage of making the solute more available by stirring it among the solvent particles.

L2 ELL IS Kinesthetic

Reading Check

Answer The negative ends of the water molecules pull on the positive ends of sugar molecules.

Quick Demo Water Polarity

Materials balloon, wool cloth

Estimated Time 5 minutes

Procedure To show the polarity of water, blow up a balloon and rub its surface with a wool cloth. Turn on the water faucet so it delivers a thin steady stream. Bring the statically charged balloon near the stream, but do not touch the balloon to it. Have students observe that the stream bends dramatically. **L2 ELL IS Visual-Spatial**

Cultural Diversity

Sandbox Trees The sap from the tall sandbox trees, found in the jungles of Central and South America, is acidic. People who fish throw this sap into lakes and streams, which have been dammed, to stun the fish so they can gather them for food. Then they remove the dams. The sap becomes sufficiently dilute, and the fish recover completely.

Differentiated Instruction

Learning Disabled As you do the various demonstrations, help students follow what you are doing by moving slowly and deliberately through each step and explaining what you are doing as you do it. Make sure all students can see what you do and can see the results. Make sure you describe the results to the class. **L1 ELL Auditory-Musical**

Mini LAB

Video Lab available.

Purpose Students will observe differences in the rates of dissolution of particles with different surface areas. **L2** **ELL** **IS**

Visual-Spatial

Materials four sugar cubes, distilled water, two glasses, two stirring rods per group

Teaching Strategy Have students do the activity twice, once stirring the sugar and once not stirring. Stirring increases rate of dissolving.

Analysis

1. The granules dissolved faster than the cubes even though they were treated identically.
2. The greater the surface area of the solute, the faster it dissolves.

Assessment

Oral Have students use their MiniLAB results and **Figure 5** to explain how the surface area of the two cubes increases when they are ground. Use **Performance Assessment in the Science Classroom**, p. 89.

Discussion

Surface Area Discuss with students how rapidly surface area increases as an object is divided into smaller pieces. Have students calculate the surface area of a 2-cm cube. $6 \times 4 \text{ cm}^2 = 24 \text{ cm}^2$. Ask students to predict how much larger the surface area would be if the cube were divided into 1-cm cubes. How many 1-cm cubes would there be? 8 What is their surface area? $8 \times 6 \times 1 \text{ cm}^2 = 48 \text{ cm}^2$ **L2**

Mini LAB

Observing the Effect of Surface Area

Procedure

1. Grind up two **sugar cubes**.
2. Place the ground sugar particles into a **medium-sized glass** and place two **unground sugar cubes** into a **similar glass**.
3. Add an equal amount of **water** at room temperature to each glass.

Analysis

1. Compare the times required to dissolve each.
2. What can you conclude about the dissolving rate and surface area?

Figure 5 Crystal size affects solubility. Large crystals dissolve in water slowly because the amount of surface area is limited.

A face of a cube is the outer surface that has four edges.

Pull apart the cube into smaller cubes of equal size. You now have 8 cubes and 48 faces.

If you divide the cube into smaller cubes that are 1 cm on a side, you will have 1,728 cubes and 10,368 faces.

756 CHAPTER 24 Solutions, Acids, and Bases

Rate of Dissolving

When two substances form a solution, the dissolving occurs at different rates. Sometimes the rate at which a solute dissolves into a solvent is fast, while other times it is slow. There are several things you can do to speed up the rate of dissolving—stirring, reducing crystal size, and increasing temperature.

Stirring How does stirring speed up the dissolving process? Think about how you make a drink from a powdered mix. After you add the mix to water, you stir it. Stirring a solution speeds up the dissolving process because it brings more fresh solvent into contact with more solute. The fresh solvent attracts the particles of solute, causing the solid solute to dissolve faster.

Crystal Size Another way to speed the dissolving of a solid in a liquid is to grind large crystals into smaller ones. Suppose you want to use a 5-g crystal of rock candy to sweeten your water. If you put the whole crystal into a glass of water, it might take several minutes to dissolve, even with stirring. However, if you first grind the crystal of rock candy into a powder, it will dissolve in the same amount of water in a few seconds.

Why does breaking up a solid cause it to dissolve faster? Breaking the solid into many smaller pieces greatly increases its surface area, as you can see in **Figure 5**. Because dissolving takes place at the surface of the solid, increasing the surface area allows more solvent to come into contact with more solid solute. Therefore, the speed of the dissolving process increases.

Active Reading

Quickwrites Let students discover what they already know about solutions, solvents, and solutes. Have students list their ideas and thoughts about these topics freely in a paragraph. Then, during or after a learning experience, share those ideas and thoughts with the class. **L2**

Applying Math

Calculate

SURFACE AREA The length, height, and width of a cube are each 1 cm. If the cube is cut in half to form two rectangles, how much new surface area has been created?

IDENTIFY the known values and the unknown value

Identify the known values:

- The cube has dimensions of $l = h = w = 1$ cm.
- The rectangular solid has a width $w = 0.5$ cm.
- The rectangular solid has a length and height $l = h = 1$ cm.
- The cube and the rectangular solids each have six faces: front and back ($h \times w$); left and right ($h \times l$); and top and bottom ($w \times l$). The total surface area of the cube or the rectangular solid is the sum of these areas, or $2(h \times w) + 2(h \times l) + 2(w \times l)$.

Identify the unknown value:

Find the total surface area of the two rectangular solids.

SOLVE the problem

The surface area of the cube is:

$$2(1 \text{ cm} \times 1 \text{ cm}) + 2(1 \text{ cm} \times 1 \text{ cm}) + 2(1 \text{ cm} \times 1 \text{ cm}) = 6 \text{ cm}^2$$

The surface area of the rectangular solid is:

$$2(1 \text{ cm} \times 0.5 \text{ cm}) + 2(1 \text{ cm} \times 1 \text{ cm}) + 2(0.5 \text{ cm} \times 1 \text{ cm}) = 4 \text{ cm}^2$$

Because there are two rectangular solids, their total surface area is:

$$4 \text{ cm}^2 + 4 \text{ cm}^2 = 8 \text{ cm}^2$$

To find out how much new surface area has been created, compare the two results:

$$8 \text{ cm}^2 - 6 \text{ cm}^2 = 2 \text{ cm}^2$$

CHECK the answer

Does your answer seem reasonable? Consider what you've done by splitting the cube in two. You have created two new faces, each with a surface area of 1 cm^2 ; therefore, the answer 2 cm^2 is correct.

Practice Problems

1. A cube of salt with a length, height, and width of 5 cm is attached along a face to another cube of salt with the same dimensions. What is the combined surface area of the new rectangular solid?
2. How much surface area has been lost?

Applying Math

Math Standards

National: 4, 6, 9

Florida: MA.B.1.4.1

Answers to Practice Problems

1. Solve the equations

• For the attached cubes:
 $h = 5 \text{ cm}, l = 5 \text{ cm}, w = 10 \text{ cm}$
 $2(5 \text{ cm} \times 10 \text{ cm}) + 2(5 \text{ cm} \times 5 \text{ cm}) + 2(10 \text{ cm} \times 5 \text{ cm})$
 $= 250 \text{ cm}^2$

• For the original cubes:

$$h = l = w = 5 \text{ cm}$$

$$2(5 \text{ cm} \times 5 \text{ cm}) + 2(5 \text{ cm} \times 5 \text{ cm}) + 2(5 \text{ cm} \times 5 \text{ cm})$$

$$= 150 \text{ cm}^2$$

2. Because there were two cubes,
 $150 \text{ cm}^2 + 150 \text{ cm}^2 = 300 \text{ cm}^2$,
 so 50 cm^2 of surface area was lost.

Fun Fact

Moisturizers have long been used to protect and rehydrate the skin. These products contain compounds called humectants and emollients that increase the water content of the skin in different ways. Humectants add water to the skin by attracting water vapor from the air. Emollients cover the skin with a layer of material that is immiscible with water. This prevents water from within the skin from evaporating.

Differentiated Instruction

Challenge Air is a solution of gases, primarily nitrogen. Ask students to discover the other gases and the relative amounts of each in air. Students can then present their research to the class in a format of their choosing. Although charts and graphs make good visual representation, challenge students to invent another creative way to illustrate their findings. L2

Post Reading

Clarify Text Have students use the Review Summary to check their notes for completion and accuracy. Remind them to look back in the text to cross-check and clarify their notes.

3 Assess

DAILY INTERVENTION

Check for Understanding

Kinesthetic Have two or three students stand in a group and have another student pull at the hand of a student in the group. Relate this activity to the job of a solvent pulling a solute into solution. Have students identify which person is the solvent and which is the solute. [L1]

Reteach

Surface Area Bring in two boxes of different sizes to represent different surface areas. Use a new crayon and color all six sides of the larger box. Then use another new crayon and color all six sides of the smaller box. Explain that the difference in surface area affected the amount of crayon that was needed to color it. [L2] **Visual Spatial**

Assessment

Content Have students work in groups to write a story or a poem about what happens to one NaCl crystal as it is put into water and dissolves. Use **Performance Assessment in the Science Classroom**, p. 157. [L2] **P**

Temperature In addition to stirring and decreasing particle size, a third way to increase the rate at which most solids dissolve is to increase the temperature of the solvent. Think about making hot chocolate from a mix. You can make the sugar in the chocolate mix dissolve faster by putting it in hot water instead of cold water. Increasing the temperature of a solvent speeds up the movement of its particles. This increase causes more solvent particles to bump into the solute. As a result, solute particles break loose and dissolve faster.

Controlling the Process Think about how the three factors you just learned about affect the rate of dissolving. Can these factors combine to further increase the rate, or perhaps control the rate of dissolving? Each technique—stirring, crushing, and heating—is known to speed up the rate of dissolving by itself. However, when two or more techniques are combined, the rate of dissolving is even faster. Consider a sugar cube placed in cold water. You know that the sugar cube eventually will dissolve. You can predict that heating the water will increase the rate by some amount. You also can predict that heat and stirring will increase the rate further. Finally, you can predict that crushing the cube combined with heating and stirring will result in the fastest rate of dissolving. Knowing how much each technique affects the rate will allow you to control the rate of dissolving more precisely.

section 1 review

Summary

What is a solution?

- A solution is a uniform mixture.
- A solution has the same composition, color, density, and taste throughout.

Solutes and Solvents

- In a solution, the solute is the substance that is being dissolved; the solvent is the substance that is doing the dissolving.

How Substances Dissolve

- The process of dissolving happens at the surface and is aided by polarity and molecular movement.

Rate of Dissolving

- Stirring, surface area, and temperature affect the rate of dissolving.

Self Check

1. **List** possible ways that phases of matter could combine to form a solution.
2. **Describe** how temperature affects the rate of dissolving.
3. **Describe** how the metal atoms in an alloy are mixed.
4. **Think Critically** Amalgams, which sometimes are used in tooth fillings, are alloys of mercury with other metals. Is an amalgam a solution? Explain.

Applying Math

5. **Find Surface Area** Calculate the surface area of a rectangular solid with dimensions $\ell = 2$ cm, $w = 1$ cm, and $h = 0.5$ cm.
6. **Calculate Percent Increase** If the length of the rectangle in question 5 is increased by 10 percent, by how much will the surface area increase?

section 1 review

1. Possible answer: liquid/liquid, solid/liquid, gas/liquid, gas/gas, solid/solid.
2. Increasing temperature causes particles to move faster which causes solutes to dissolve faster.
3. Metals are melted, mixed evenly, then cooled to a solid.
4. Yes, one metal acts as the solute while the other metal acts as a solvent.
5. $2(2 \text{ cm} \times 1 \text{ cm}) + 2(2 \text{ cm} \times 0.5 \text{ cm}) + 2(1 \text{ cm} \times 0.5 \text{ cm}) = 7 \text{ cm}^2$
6. new $\ell = 2.2$ cm; therefore, new surface area = 7.6 cm.

$$\left[\frac{(7.6 \text{ cm} - 7 \text{ cm})}{7 \text{ cm}} \right] \times 100 = 8.5\% \text{ increase}$$

Solubility and Concentration

Reading Guide

FCAT Vocabulary

What You'll Learn

- **Define** the concept of solubility.
- **Identify** how to express the concentration of solutions.
- **List** and define three types of solutions.
- **Describe** the effects of pressure and temperature on the solubility of gases.

Why It's Important

Solutions such as medicine and lemonade work and taste a particular way because of the specific solution concentrations.

Review Vocabulary

substance: element or compound that cannot be broken down into simpler components

New Vocabulary

- ★ **solubility**
- ★ **concentration**
 - saturated solution
 - unsaturated solution
 - supersaturated solution

How much can dissolve?

You can stir several teaspoons of salt into water, and the salt will dissolve. However, if you continue adding salt, eventually the point is reached when no more salt dissolves and the excess salt sinks to the bottom of the glass. This indicates how soluble salt is in water. **Solubility** (sol yuh BIH luh tee) is the maximum amount of a solute that can be dissolved in a given amount of solvent at a given temperature.

Reading Check What is solubility?

Comparing Solubilities The amount of a solute that can dissolve in a solvent depends on the nature of these substances. **Figure 6** shows two beakers with the same volume of water and two different solutes. In one beaker, 1 g of solute A dissolves completely, but additional solute does not dissolve and falls to the bottom of the beaker. On the other hand, 1 g of solute B dissolves completely, and two more grams also dissolve before solute begins to fall to the bottom. You can conclude that substance B is more soluble than substance A, if the temperature of the water is the same in both beakers. **Table 1** shows how the solubility of several substances varies at 20°C. For solutes that are gases, the pressure also must be given.

1 g
Solute A

3 g
Solute B

Figure 6 Substance B is more soluble in water than substance A is at the same temperature.

Hydrogen	0.00017
Oxygen	0.005
Carbon dioxide	0.16

*at normal atmospheric pressure

Concentration

Suppose you add one teaspoon of lemon juice to a glass of water to make lemonade. Your friend adds four teaspoons of lemon juice to another glass of the same size. What is the difference between these two glasses of lemonade? The difference between the two drinks is the amount of water present compared to the amount of lemon juice. The **concentration** describes how much solute is present in a solution compared to the amount of solvent. A concentrated solution is one in which a large amount of solute is dissolved in the solvent. A dilute solution is one that has a small amount of solute in the solvent.

Precise Concentrations How much real fruit juice is there in one of those boxed fruit drinks? You can read the label to find out. *Concentrated* and *dilute* are not precise terms. Concentrations of solutions can be described precisely. One way is to state the percentage by volume of the solute. The percentage by volume of the juice in the bottled drink shown in **Figure 7** is 10 percent. Adding 10 mL of juice to 90 mL of water makes 100 mL of this drink. Commonly, fruit-flavored drinks can have ten percent or less fruit juice. Generally, if two or more liquids are being mixed, the concentration is given in percentage by volume.

Figure 7 The concentrations of fruit juices often are given in percent by volume, as these are. Concentrations commonly range from 10 percent to 100 percent juice.

Identify the product that has the highest concentration.

Differentiated Instruction

Learning Disabled To show students the difference between saturated and unsaturated solutions, add 36 g of sodium chloride to 100-mL of room temperature water. Stir the salt until it is completely dissolved. Place a small amount of this solution in a petri dish. Place a small amount of the same solution in a second petri dish and add water to

make it unsaturated. Place both petri dishes on the overhead projector. Have a student drop a crystal of salt into each dish and slowly stir both solutions. The crystal will dissolve in the unsaturated solution, but it will remain visible in the saturated solution.

Types of Solutions

How much solute can dissolve in a given amount of solvent? That depends on a number of factors, including the solubility of the solute. Here you will examine the types of solutions based on the amount of a solute dissolved.

Saturated Solutions If you add 35 g of copper(II) sulfate, CuSO_4 , to 100 g of water at 20°C , only 32 g will dissolve. You have a saturated solution because no more copper(II) sulfate can dissolve. A **saturated solution** is a solution that contains all the solute it can hold at a given temperature. However, if you heat the mixture to a higher temperature, more copper(II) sulfate can dissolve. Generally, as the temperature of a liquid solvent increases, the amount of solid solute that can dissolve in it also increases. **Table 2** shows the amounts of a few solutes that can dissolve in 100 g of water at different temperatures to form saturated solutions. Some of these data also are shown on the accompanying graph.

Solubility Curves Each line on the graph from **Table 2** is called a solubility curve for a particular substance. You can use a solubility curve to determine how much solute will dissolve at any temperature given on the graph. For example, about 78 g of KBr (potassium bromide) will form a saturated solution in 100 g of water at 47°C . How much NaCl (sodium chloride) will form a saturated solution with 100 g of water at the same temperature?

Unsaturated Solutions An **unsaturated solution** is any solution that can dissolve more solute at a given temperature. Each time a saturated solution is heated to a higher temperature, it generally becomes unsaturated. The term *unsaturated* isn't precise. If you look at **Table 2**, you'll see that at 20°C , 35.9 g of NaCl (sodium chloride) forms a saturated solution in 100 g of water. However, an unsaturated solution of NaCl could be any amount less than 35.9 g in 100 g of water at 20°C .

Reading Check What happens to a saturated solution if it is heated?

Table 2 Solubility of Compounds in g/100 g of Water

Compound	0°C	20°C	100°C
Copper(II) sulfate	23.1	32.0	114
Potassium bromide	53.6	65.3	104
Potassium chloride	28.0	34.0	56.3
Potassium nitrate	13.9	31.6	245
Sodium chlorate	79.6	95.9	204
Sodium chloride	35.7	36.0	39.2
Sucrose (sugar)	179.2	203.9	487.2

Text Question Answer
approximately 37 g of NaCl

Inquiry Lab

Saturation Point
Purpose Students witness the saturation point of a solution of their choice and have the opportunity to compare results with others for a wider experience.
Possible Materials water, rubbing alcohol, juices or drinks for solvents; granular sugar, powdered sugar, flour, salt for solutes, balance

Estimated Time 30 minutes
Give each student a beaker and have them add 50 mL of the solvent of their choice. Then instruct them to begin adding 5g of solute of their choice, slowly and with stirring. Have students keep close track of how much solute they add until the solution becomes saturated. Encourage students to repeat the activity to find out how other solutes work with the solvent they chose or how other solvents work with the solute they chose. Prepare a class chart of the results.

- Teaching Strategies**
- Discuss this activity before starting and let the students brainstorm possible solutes and solvents.
 - Do not limit their possible materials to only those substances that will dissolve.
 - Encourage students to investigate the variables that apply to this activity, such as volume of solvent, degree of agitation, and temperature. [L2]

For additional inquiry activities, see *Science Inquiry Lab Manual*.

Reading Check

Answer It may become unsaturated.

Caption Answer
Figure 7 the product labeled “100% pure orange juice”

Reading Strategy

Use Graphs Have students write a sentence comparing the general effect of increasing temperature on the solubility of sodium chloride and potassium nitrate. Tell students that all the information needed for this task can be found in **Table 2**. Discuss students' sentences and analyze their accuracy based on **Table 2**.

Curriculum Connection

Math Ask students to refer to **Table 2** and answer the following question. If you were to graph the solubility of a solute on the y axis and the temperature of the solution on the x axis, which solute would have the line with the steepest slope, potassium chloride or sodium chloride? potassium chloride [L2]

Make a Model

Beaker Solutions On the board draw three identical oversized beakers. Draw the same number of small circles in each beaker. These represent particles of a solvent. Ask students to copy your drawings and add, using a different color of pen or pencil, circles in the beakers to represent unsaturated, saturated, and supersaturated solutions. **L1** **TS**

Analytical-Mathematical

Quick Demo

Gas in Solution

Materials full, unopened bottle of soda (any size)

Estimated Time 10 minutes

Procedure Open a soda bottle. Point out that when a soda is sealed, pressure keeps the gas in solution. Once opened, pressure is reduced and then bubbles become visible again.

Use an Analogy

Saturated Class Describe the types of solutions using the analogy of adding students to a classroom. In a room with 25 desks, a class with fewer than 25 students is analogous to an unsaturated solution. More students can be added to fill the desks. The 25th student takes the last desk and makes the classroom saturated. Adding more students beyond 25 causes some students to be displaced from desks and fall out into the aisles, representing precipitation. **L1**

ScienceOnline

Topic: Crystallization

Visit fl.gpscience.com for Web links to information about crystals and crystallization.

Activity Find instructions for a safe "do-it-yourself" home crystallization experiment. Grow the crystals as directed and share the results with the class.

Supersaturated Solutions If you make a saturated solution of potassium nitrate at 100°C and then let it cool to 20°C, part of the solute comes out of solution. This is because the solvent cannot hold as much solute at the lower temperature. Most other saturated solutions behave in a similar way when cooled. However, if you cool a saturated solution of sodium acetate from 100°C to 20°C without disturbing it, no solute comes out. At this point, the solution is supersaturated. A **supersaturated solution** is one that contains more solute than a saturated solution at the same temperature. Supersaturated solutions are unstable. For example, if a seed crystal of sodium acetate is dropped into the supersaturated solution, excess sodium acetate crystallizes out, as shown in **Figure 8**.

Solution Energy As the supersaturated solution of sodium acetate crystallizes, the solution becomes hot. Energy is given off as the sodium acetate forms crystals. Some portable heat packs use crystallization from supersaturated solutions to produce heat. After crystallization, the heat pack can be reused by heating it to again dissolve all the solute.

Substances, such as ammonium nitrate, draw energy from their surroundings to dissolve. This is what happens when a cold pack is activated to treat minor injuries or to reduce swelling. When the inner bags of ammonium nitrate and water are broken, the ammonium nitrate draws energy from the water, which causes the temperature of the water to drop, which makes the pack cool.

Figure 8 A supersaturated solution is unstable.

Explain why this is so.

A seed crystal of sodium acetate is added to a supersaturated solution of sodium acetate.

Reading Check

Why is energy given off between ions and water molecules?

Excess solute immediately crystallizes from solution.

The crystallization reaction draws solute from the solution.

LAB DEMONSTRATION

Purpose to show that dissolved ionic compounds conduct an electrical current

Materials conductivity tester, distilled water, NaCl, Epsom salt, rubbing alcohol, sugar

Preparation List the solutes on the board. Dissolve each in distilled water.

Procedure Test the conductivity of each solution. Make sure students can see the results of each test.

Expected Outcome NaCl and Epsom salt solutions will conduct electricity; alcohol and sugar solutions will not.

Assessment

What occurs in the conducting solutions? Ions are moving out of crystals and into water where they can move in the solution and conduct electricity. Why don't the other solutions conduct electricity? The solutes in the other solutions don't form ions. **L2**

Solubility of Gases

When you shake an opened bottle of soda, it bubbles up and may squirt out. Shaking or pouring a solution of a gas in a liquid causes gas to come out of solution. Agitating the solution exposes more gas molecules to the surface, where they escape from the liquid.

Pressure Effects What might you do if you want to dissolve more gas in a liquid? One thing you can do is increase the pressure of that gas over the liquid. Soft drinks are bottled under increased pressure. This increases the amount of carbon dioxide that dissolves in the liquid. When the pressure is released, the carbon dioxide bubbles out, as shown in **Figure 9**.

Temperature Effects Another way to increase the amount of gas that dissolves in a liquid is to cool the liquid. This is just the opposite of what you do to increase the speed at which most solids dissolve in a liquid. Imagine what happens to the carbon dioxide when a bottle of soft drink is opened. Even more carbon dioxide will bubble out of a soft drink as it gets warmer.

Figure 9 Solutions of gases behave differently from those of solids or liquids. This soda is bottled under pressure to keep carbon dioxide in solution. When the bottle is opened, pressure is released and carbon dioxide bubbles out of solution.

Reading Check

Answer New bonds are formed.

Caption Answer

Figure 8 because a change in temperature causes solute to fall out

Post Reading

Question a Partner Place students in pairs and have them read their sentences related to **Table 2** to each other. Have each partner ask the other questions about their sentences, probing for deeper meaning and understanding.

3 Assess

section 2 review

Summary

How much can dissolve?

- Solubility tells how much solute can dissolve in a solvent at a particular temperature.

Concentration

- A concentrated solution has a larger amount of dissolved solute. A dilute solution has a smaller amount of dissolved solute.

Types of Solutions

- Saturated, unsaturated, and supersaturated solutions are defined by how much solute is dissolved.
- Solubility curves help predict how much solute can dissolve at a particular temperature.
- Some supersaturated solutions absorb or give off energy.

Solubility of Gases

- Pressure and temperature affect gases in solution. High pressure and low temperature allow more gas to dissolve.

Self Check

- Explain** Do all solutes dissolve to the same extent in the same solvent? How do you know?
- Interpret** from **Table 2** the mass of sugar that would have to be dissolved in 100 g of water to form a saturated solution at 20°C.
- Determine** which solution is more concentrated: 17 g of solute X dissolved in 100 mL of water at 23°C or 26 g of solute Z dissolved in 100 mL of water at 23°C.
- Identify** the type of solution you have if, at 35°C, the solute continues to dissolve as you add more.
- Think Critically** Explain how keeping a carbonated beverage capped helps keep it from going "flat."

Applying Math

- Calculate Cost** By volume, orange drink is ten percent each of orange juice and corn syrup. A 1.5-L can of the drink costs \$0.95. A 1.5-L can of orange juice is \$1.49, and 1.5 L of corn syrup is \$1.69. Per serving, does it cost less to make your own orange drink or buy it?

DAILY INTERVENTION

Check for Understanding

Honey Crystals Describe, or bring to class if available, an old jar of honey. Ask students to describe why there are crystals of sugar forming in the previously smooth solution. As the water evaporates from the solution, the dissolved sugar becomes more concentrated. As the concentration exceeds the saturation limit, sugar will begin to precipitate, crystallizing out of the solution. **L2** **IS** **Linguistic**

Reteach

Aromas Open a small bottle of ammonia in the back of the room without telling students. Ask if anyone can detect any type of chemical aroma. As the ammonia fumes mix in the air, point out to students that the air is diluting the ammonia. **L2**

section 2 review

- No; you can determine this experimentally.
- 203.9 g
- solute Z
- unsaturated

- When capped, carbon dioxide stays in solution, which keeps the soda "fizzy."
- Making it is cheaper. If you were making 1,500 mL of orange drink you would need 150 mL of orange juice @ \$1.49/1,500 mL = 14.9

cents per 150 mL; 150 mL of syrup @ \$1.69/1,500 mL = 16.9 cents per 150 mL; so, to make 1,500 mL of drink you need only 14.9 + 16.9 cents = 31.8 cents of ingredients per 1,500 mL of drink

Assessment

Performance Have students use the data in **Table 2** to plot solubility versus temperature for sucrose. The line slopes up, and the second line slopes down. Use **PASC**, p. 111. **L2** **P**

Acids, Bases, and Salts

1 Motivate

An editable Microsoft® PowerPoint® presentation is available on **Interactive Chalkboard** CD-ROM.

Bellringer

Tie to Prior Knowledge

Material States Ask students to describe situations in which the boiling point or the freezing point of a material was changed. If they have trouble, explain that adding antifreeze to automobile radiators raises the boiling point. Explain that they will learn how this process works. L2

Activate Background Knowledge

Ask students if they have heard of acid indigestion. Tell them this is a burning feeling in your stomach and sometimes people take pink or white chalky medicine to neutralize the burning. Tell them that they will learn about acids and bases and how they interact.

Reading Guide

FCAT Vocabulary

What You'll Learn

- **Compare and contrast** acids and bases and identify the characteristics they have.
- **Examine** some formulas and uses of common acids and bases.
- **Determine** how the processes of ionization and dissociation apply to acids and bases.

Why It's Important

Acids and bases are found almost everywhere—from fruit juice and gastric juice to soaps.

Review Vocabulary

electrolyte: compound that breaks apart in water, forming charged particles (ions) that can conduct electricity

New Vocabulary

- ★ **acid**
- ★ **indicator**
- ★ **base**

Acids

What comes to mind when you hear the word *acid*? Do you think of a substance that can burn your skin or even burn a hole through a piece of metal? Do you think about sour foods such as those shown in **Figure 10**? Although some acids can burn and are dangerous to handle, most acids in foods are safe to eat. What acids have in common, however, is that they contain at least one hydrogen atom that can be removed when the acid is dissolved in water.

Figure 10 The acids in these common foods give each their distinctive sour taste.

Properties of Acids When an acid dissolves in water, some of the hydrogen is released as hydrogen ions, H^+ . An **acid** is a substance that produces hydrogen ions in a water solution. It is the ability to produce these ions that gives acids their characteristic properties. When an acid dissolves in water, H^+ ions interact with water molecules to form H_3O^+ ions, which are called hydronium ions (hi DROH nee um • I ahnz).

Acids have several common properties. For one thing, all acids taste sour. The familiar, sour taste of many foods is due to acids. However, taste never should be used to test for the presence of acids. Some acids can damage tissue by producing painful burns. Acids are corrosive. Some acids react strongly with certain metals, eating away the metals and forming metallic compounds and hydrogen gas. Acids also react with indicators to produce predictable changes in color. An **indicator** is an organic compound that changes color in acids and bases. For example, the indicator litmus paper turns red in acid.

Common Acids Many foods contain acids. In addition to citric acid in citrus fruits, lactic acid is found in yogurt and buttermilk, and food, such as pickles, contain vinegar, also known as acetic acid. Your stomach uses acid to help digest your food. At least four acids (sulfuric, phosphoric, nitric, and hydrochloric) play roles in industrial applications.

Reading Check Which four acids are important for industry?

Table 3 lists the names and formulas of a few acids, their uses, and some properties. Three acids are used to make fertilizers; most of the nitric acid and sulfuric acid and approximately 90 percent of phosphoric acid produced are used for this purpose. Many acids can burn, but sulfuric acid can burn by removing water from your skin as easily as it takes water from sugar, as shown in **Figure 11**.

Table 3 Common Acids and Their Uses

Name, Formula	Use	Other Information
Acetic acid, CH_3COOH	Food preservation and preparation	When in solution with water, it is known as vinegar.
Acetylsalicylic acid, $\text{HOOC}-\text{C}_6\text{H}_4-\text{OOCCH}_3$	Pain relief, fever relief, to reduce inflammation	Known as aspirin
Ascorbic acid, $\text{H}_2\text{C}_6\text{H}_6\text{O}_6$	Antioxidant, vitamin	Called vitamin C
Carbonic acid, H_2CO_3	Carbonated drinks	Involved in cave, stalactite, and stalagmite formation
Hydrochloric acid, HCl	Digestion as gastric juice in stomach, to clean steel in a process called pickling	Commonly called muriatic acid
Nitric acid, HNO_3	To make fertilizers	Used to produce nitrogen fertilizers
Phosphoric acid, H_3PO_4	To make detergents, fertilizers, and soft drinks	Slightly sour but pleasant taste, detergents containing phosphates cause water pollution
Sulfuric acid, H_2SO_4	Car batteries, to manufacture fertilizers and other chemicals	Dehydrating agent, causes burns by removing water from cells

SECTION 3 Acids, Bases, and Salts 765

Reading Strategy

Tables Have students keep a data table labeled Acids and Bases. Ask students to list common and chemical names of acids and bases under the appropriate headings. Remind them to read the text carefully as they complete their charts.

Curriculum Connection

Art Etching is using the reaction between an acid and a metal to make a piece of art. Have students find out more about this process and make posters illustrating it. A metal plate, usually copper or zinc, is coated with acid-resistant resin. The artist draws lines through the resin, then puts the plate in an acid bath. The acid reacts with the metal exposed by the drawing and not through the resin. **L2 P AS Visual-Spatial**

Figure 11 When sulfuric acid is added to sugar, the mixture foams, removing hydrogen and oxygen atoms as water and leaving air-filled carbon.

2 Teach

Activity

Acid Formulas Have students note the formulas of the inorganic acids listed in **Table 3**. Ask what they observe about the way formulas of these acids are typically written. Chemists commonly indicate that a compound is an acid by writing the formula with "H" as the first element.

L2 AS Logical-Mathematical

Use Science Words

Word Meaning Have students use the word *indicator* in a sentence, and then explain how the meaning of *indicator* in their sentence parallels its meaning in the context of acid and base identification. **L2 AS Linguistic**

Visual Learning

Table 3 If an acid contains a structure that includes COOH , it is an organic acid. Other acids, including H_2CO_3 , are inorganic. Have students work in small groups to classify the acids from **Table 3** as organic or inorganic. All are inorganic except acetic acid and acetylsalicylic acid. **L2 AS Linguistic**

Reading Check

Answer sulfuric, phosphoric, nitric, and hydrochloric acids

Visual Learning

Figure 11 This reaction produces irritating fumes and should not be attempted in the classroom.

Mini LAB

Purpose to observe how an indicator changes color as a base is neutralized [L2] (ELL)

AS Kinesthetic

Materials water, 250-mL beaker, 1 M HCl, universal indicator, antacid tablets, graduated cylinder, dropper

Teaching Strategy A blue or violet color may occur when the HCl is added, depending on the brand of antacid used.

Analysis

1. The color changed from red to orange to yellow to green.
2. The base neutralized the HCl, changing the color of the indicator.

Assessment

Portfolio Have students write complete lab reports of this activity in their Science Journals. Encourage them to include both diagrams and written descriptions. Make sure they include the materials used, the procedure, and all of their observations. Use **Performance Assessment in the Science Classroom**, p. 119.

P [L2]

Quick Demo

Test a Base

Materials drain cleaner, distilled water, litmus

Estimated Time 15 minutes

Procedure Add a small amount (less than 5 mL) of drain cleaner to distilled water. Test the solution with litmus to demonstrate the base properties of the cleaner. **WARNING:** Keep the solution out of reach of students. Dispose of it properly. [L2] (ELL)

AS Visual-Spatial

Caption Answer

Figure 12 slipperiness

Mini LAB

Observing Acid Relief

WARNING: Do not eat antacid tablets.

Procedure

1. Add 150 mL of water to a 250-mL beaker.
2. Add three drops of 1M HCl and 12 drops of universal indicator.
3. Observe the color of the solution.
4. Add an antacid tablet and observe for 15 min.

Analysis

1. Describe any changes that took place in the solution.
2. Explain why these changes occurred.

Bases

You might not be as familiar with bases as you are with acids. Although you eat some foods that are acidic, you don't consume many bases. Some foods, such as egg whites, are slightly basic. Another example of basic materials is baking powder, which is found in some foods. Medicines, such as milk of magnesia and antacids, are basic, too. Still, you come in contact with many bases every day. Each time you wash your hands using soap, you are using a base. One characteristic of bases is that they feel slippery, like soapy water. Bases are important in many types of cleaning materials, as shown in **Figure 12**. Bases are important in industry, also. For example, sodium hydroxide is used in the paper industry to separate fibers of cellulose from wood pulp. The freed cellulose fibers are made into paper.

Bases can be defined in two ways. Any substance that forms hydroxide ions, OH^- , in a water solution is a **base**. In addition, a base is any substance that accepts H^+ from acids. The definitions are related, because the OH^- ions produced by some bases do accept H^+ ions.

✓ Reading Check What are the two definitions of a base?

Properties of Bases One way to think about bases is as the complements, or opposites, of acids. Although acids and bases share some common features, bases have their own characteristic properties. In the pure, undissolved state, many bases are crystalline solids. In solution, bases feel slippery and have a bitter taste. Like strong acids, strong bases are corrosive, and contact with skin can result in severe burns. Taste and touch never should be used to test for the presence of a base or an acid. Finally, like acids, bases react with indicators to produce changes in color. The indicator litmus turns blue in bases.

Figure 12 Bases commonly are found in many cleaning products used around the home.

Identify the property of bases evident in soaps.

766 CHAPTER 24 Solutions, Acids, and Bases

Teacher FYI

Base Attractions All bases attract H^+ to a pair of unshared electrons in their structures. OH^- ions have a negative charge, which helps attract positive H^+ ions. Bases

containing nitrogen have an unshared pair of electrons around the nitrogen. Typically, nitrogen-containing bases are not as strong as OH^- -containing bases.

Figure 13 Two applications of bases are shown here.

Aluminum hydroxide is a base used in water-treatment plants. Its sticky surface collects impurities, making them easier to filter from the water.

Common Bases You probably are familiar with many common bases because they are found in cleaning products used in the home. These and some other bases are shown in **Table 4**, which also includes their uses and some information about them. **Figure 13** shows two uses of bases that you might not be familiar with.

Table 4 Common Bases and Their Uses

Name, Formula	Use	Other Information
Aluminum hydroxide, $\text{Al}(\text{OH})_3$	Color-fast fabrics, antacid, water purification as shown in Figure 13	Sticky gel that collects suspended clay and dirt particles on its surface
Calcium hydroxide, $\text{Ca}(\text{OH})_2$	Leather-making, mortar and plaster, to lessen acidity of soil	Called caustic lime
Magnesium hydroxide, $\text{Mg}(\text{OH})_2$	Laxative, antacid	Called milk of magnesia when in water
Sodium hydroxide, NaOH	To make soap, oven cleaner, drain cleaner, textiles, and paper	Called lye and caustic soda; generates heat (exothermic) when combined with water, reacts with metals to form hydrogen
Ammonia, NH_3	Cleaners, fertilizer, to make rayon and nylon	Irritating odor that is damaging to nasal passages and lungs

Some drain cleaners contain NaOH , which dissolves grease, and small pieces of aluminum. The aluminum reacts with NaOH , producing hydrogen and dislodging solids, such as hair.

IDENTIFYING

Misconceptions

OH Bases Most of the bases examined in this section have OH bonded to a metal. Students may have seen the OH symbols connected to other compounds called alcohols. This does not make alcohols fit the definition of a base. The —OH in an alcohol is called a hydroxyl group and is not the same thing as the hydroxide ion, OH^- .

Fun Fact

The formula for caffeine, the stimulant found in coffee, tea, and many soft drinks, is $\text{C}_8\text{H}_{10}\text{N}_4\text{O}_2$. Caffeine is a weak acid with a pH of 6.9. Caffeinated beverages may stimulate the secretion of stomach acid, which may worsen ulcer symptoms.

Use an Analogy

Football Pass In a football game, a quarterback holding the ball cannot complete a pass unless a receiver catches the ball. An H^+ ion from an acid is like the football. The quarterback (the acid) must have a receiver (the base) to receive the football (the H^+ ion) to complete the pass (the reaction between the acid and the base). This could be demonstrated in class with a foam football labeled H^+ . **L1** **ELL** **LS**
Kinesthetic

Differentiated Instruction

Challenge Amino acids make up the building blocks of proteins. Write out the structure of the amino acid glycine, $\text{NH}_2\text{CH}_2\text{COOH}$. Ask students to identify the areas of the molecule that cause it to have acidic properties. **The H at the end of**

COOH can be donated to produce H^+ ions. Also ask students to look for another area that allows it to have base properties. The N atom has unshared electrons that can attract and accept H^+ ions, as bases do. **L3 **IS** Logical-Mathematical**

Acidic Stings HCOOH , or formic acid, has the simplest structure of the organic acids. One of the first preparations of this acid included the crushing and heating of ants and the recovery of the vapor that contained the acid.

Discussion

Natural Acids and Bases Talk about other examples of acids and bases in nature. Students may not know of specific examples, but the discussion could focus on logical possibilities such as defense mechanisms.

Make a Model

Ionization To illustrate the dissociation that takes place when an acid is dissolved in water, have students hold a capped ink pen in the right hand. On your signal, have them use the left hand to remove the cap and cover it in that hand. In this model, water (the left hand) detaches H^+ (the pen cap) from an acid (the pen) and surrounds and holds it. This same process takes place with billions of acid molecules as they dissociate in water. **L1 ELL K Kinesthetic**

Visual Learning

Figure 14 With students, review the two parts of the illustration. Draw a diagram on the chalkboard showing how hydrogen chloride gas molecules form hydronium ions in water. Draw a similar diagram for formic acid. **L2 K Visual-Spatial**

Caption Answer

Figure 15 It would speed it up by providing more surface area, allowing more of the antacid to come in contact quickly with stomach acid.

When sodium hydroxide dissolves in water, a sodium ion and a hydroxide ion are produced.

When hydrogen chloride dissolves in water, a hydronium ion and a chloride ion are produced.

Figure 14 When acids and bases are dissolved in water, they produce ions. Acids produce hydronium ions in water. Bases produce hydroxide ions in water.

Acidic Stings Some ants add sting to their bite by injecting a solution of formic acid. In fact, formic acid was named for ants, which make up the genus *Formica*. Still, ants are considered tasty treats by many animals. For example, one woodpecker called a flicker has saliva that is basic enough to take the sting out of ants. Research the chemical formula and physical properties of formic acid.

Solutions of Acids and Bases

Many of the products that rely on the chemistry of acids and bases are solutions, such as the cleaning products and food products mentioned previously. Because of its polarity, water is the main solvent in these cleaning products.

Dissociation of Acids You have learned that substances such as HCl , HNO_3 , and H_2SO_4 are acids because of their ability to produce hydrogen ions (H^+) in water. When an acid dissolves in water, the negative areas of nearby water molecules attract the positive hydrogen in the acid. The acid dissociates into ions and the hydrogen atom combines with a water molecule to form hydronium ions (H_3O^+). Dissociation is the process in which an ionic solid separates into its positive and negative ions. An acid can more accurately be described as a compound that produces hydronium ions when dissolved in water, as shown in **Figure 14**.

Dissociation of Bases Compounds that can form hydroxide ions (OH^-) in water are classified as bases. If you look at **Table 4**, you will find that most of the substances listed contain $-\text{OH}$ in their formulas. When bases that contain $-\text{OH}$ dissolve in water, the negative areas of nearby water molecules attract the positive ion in the base. The positive areas of nearby water molecules attract the $-\text{OH}$ of the base. The base dissociates into a positive ion and a negative ion—a hydroxide ion (OH^-). This process also is shown in **Figure 14**. Unlike in acid dissociation, water molecules do not combine with the ions formed from the base.

Reading Check

What ions form when acids and bases dissolve in water?

Science Journal

Oil of Vitriol Sulfate compounds used to be called vitriols because the compounds look glassy. The old name for sulfuric acid was *oil of vitriol*. The words *vitriol* and *vitriolic* have taken on broader meanings. Ask students to write the meaning of *vitriol* in their Science Journals and explain how it is connected to sulfuric acid. *Vitriol* means “something caustic,” or “virulence of feeling or speech.” **L2**

Differentiated Instruction

Visually Impaired **Figure 14** is referred to several times in the teaching suggestions; therefore, this figure should be made accessible to visually impaired students. Bring models of the molecules in the figure and have sighted students work with visually impaired students to clarify the structures.

Neutralization Advertisements for antacids claim that these products neutralize the excess stomach acid that causes indigestion. Normally, gastric juice is acidic. Too much acid can produce discomfort. Antacids contain bases or other compounds containing sodium, calcium, magnesium, or aluminum that react with acids to lower acid concentration. **Figure 15** shows what happens when you ingest an antacid tablet containing sodium bicarbonate, NaHCO_3 . The acid (HCl) is neutralized by the base (NaHCO_3).

Neutralization is a chemical reaction between an acid and a base that takes place in a water solution. When HCl is neutralized by NaOH , hydronium ions from the acid combine with hydroxide ions from the base to produce water.

Acid-Base Reactions The following general equation represents acid-base reactions in water. A few common salts are listed in **Table 5**.

Acid-Base Reactions

Salt Formation The acid-base equation accounts for only half of the ions in the solution. The remaining ions react to form a salt. A salt is a compound formed when the negative ions from an acid combine with the positive ions from a base. In the reaction between HCl and NaOH , the salt formed in water solution is sodium chloride.

Table 5 Some Common Salts and Their Uses

Name, Formula	Common Name	Uses
Sodium chloride, NaCl	Salt	Food, manufacture of chemicals
Sodium hydrogen carbonate, NaHCO_3	Sodium bicarbonate, baking soda	Food, antacids
Calcium carbonate, CaCO_3	Calcite, chalk	Manufacture of paint and rubber tires

Figure 15 An antacid tablet reacts in your stomach much as it does in this dilute HCl . Many antacid tablets are made to be chewed before they are swallowed. **Explain** how chewing the tablet would affect the rate of the reaction.

Quick Demo Produce a Salt

Materials zinc metal piece, HCl (5 mL, 1M), 2 test tubes, wood splint

Estimated Time 15 minutes

Procedure Place a pea-size piece of zinc metal in a medium-sized test tube. Add about 5 mL of 0.1M HCl to the zinc metal. **WARNING:** Handle HCl with care. Wear goggles, an apron, and gloves. Using a test-tube holder, invert another test tube over the first to collect the gas (H_2) that is generated. Then bring a glowing splint near the mouth of the second tube. The hydrogen will give a small “bark” as the hydrogen and oxygen react. **WARNING:** Wear goggles, ensure that students wear goggles, and demonstrate a safe distance from students. Ask students to balance the equation and name the salt that is produced. $\text{Zn} + 2\text{HCl} \rightarrow \text{H}_2 + \text{ZnCl}_2$; zinc chloride **L3**

IS Logical-Mathematical

Discussion

Base/Acid Prediction Ask students to use the information in **Table 3** to predict the acid and base that most likely produced each salt.

NaCl : NaOH ; HCl
 NaHCO_3 : NaOH ; H_2CO_3
 CaCO_3 : $\text{Ca}(\text{OH})_2$; H_2CO_3
 KNO_3 : KOH ; HNO_3
 K_2CO_3 : KOH ; H_2CO_3
 Na_3PO_4 : NaOH ; H_3PO_4
 NH_4Cl : NH_3 ; HCl

Science Journal

Epsom Salt Another salt students may know is Epsom salt. Have them find out the chemical formula for Epsom salt, what it is used for, and how it was named. Have them record their findings in their Science Journals. Epsom salt is $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$. It is used for soaking bruises and sprains. It was named after the mineral-rich waters of Epsom, England, which contained magnesium sulfate. **L2** **IS** Linguistic

Differentiated Instruction

Learning Disabled React a small amount of dilute HCl with the same amount of dilute NaOH . Gently boil away the liquid. Collect the white residue and show the resulting salt (NaCl) of the neutralization reaction. **WARNING:** Do not taste the salt as it may contain impurities. **L1** **IS** Visual-Spatial

Reading Check

Answer NH_3 removes H^+ from water to leave behind OH^- ions and form NH_4^+ .

Post Reading

Science Journal In their Science Journals have students summarize the process by which bases neutralize acids. Tell students to look back in the text to ensure accuracy. Remind students that rereading is often essential for comprehension. Many people must look at technical texts several times to understand what they have read.

3 Assess

DAILY INTERVENTION

Check for Understanding

Linguistic Conduct a discussion about the properties of acids and bases by going around the room and having each student make a true statement about what they've learned in this section. [L2]

Reteach

Litmus Test Provide several unlabeled dilute solutions of acids and bases. Give students litmus paper to test the solutions to determine which are acids and which are bases. *Litmus is red in an acid and blue in a base.* [L2] **Visual-Spatial**

Assessment

Performance Ask students to write the balanced chemical equation for the reaction of ammonium hydroxide, NH_4OH with hydrogen chloride, HCl .
 $\text{NH}_4\text{OH} + \text{HCl} \rightarrow \text{NH}_4\text{Cl} + \text{H}_2\text{O}$ [L2]

Figure 16 Ammonia reacts with water to produce some hydroxide ions; therefore, it is a base.

Scienceonline

Topic: Cleaner Chemistry

Visit fl.gpscience.com for Web links to information about the dangers of mixing ammonia cleaners with chlorine or hydrochloric acid cleaners.

Activity Visit the cleaning products and laundry sections of the grocery store. Read the labels on several products. Make a list of products that include warnings on the labels and those that do not. Share your findings with the class.

An Exception Ammonia is a base that does not contain -OH . In a water solution, dissociation takes place when the ammonia molecule attracts a hydrogen ion from a water molecule, forming an ammonium ion (NH_4^+). This leaves a hydroxide ion (OH^-), as shown in **Figure 16**.

Reading Check How does ammonia react in a water solution?

Ammonia is a common household cleaner. However, products containing ammonia never should be used with other cleaners that contain chlorine or sodium hypochlorite, such as some bathroom toilet-bowl cleaners and bleach. A reaction between sodium hypochlorite and ammonia produces the toxic gases hydrazine and chloramine. Breathing these gases can severely damage lung tissues and cause death.

The reactions of acids and bases are important to the chemistry of living systems, the environment, and many industrial processes.

section 3 review

Summary

Acids

- Acids, when dissolved in water, release H^+ , which forms hydronium ions (H_3O^+).
- Acids are sour tasting, corrosive, and reactive with indicators.

Bases

- Bases, when dissolved in water, form OH^- .
- Bases are slippery, have a bitter taste, are corrosive, and are reactive with indicators.

Solutions of Acids and Bases

- The polar nature of water allows acids and bases to dissolve in water.
- Dissociation is the separation of substances, such as acids and bases, into ions in water.

Self Check

1. **Identify** three important acids and three important bases and describe their uses.
2. **Describe** an indicator.
3. **Predict** what metallic compound forms when sulfuric acid reacts with magnesium metal.
4. **Infer** If an acid donates H^+ and a base produces OH^- , what compound is likely to be produced when acids react with bases?
5. **Think Critically** Vinegar contains acetic acid, CH_3COOH . What salt is formed if acetic acid reacts with sodium hydroxide, NaOH ?

Applying Math

6. **Calculate** the molecular weight of acetylsalicylic acid, $\text{C}_9\text{H}_8\text{O}_4$.

section 3 review

1. Accept all reasonable responses.
2. an organic compound that changes color in acid or base
3. magnesium sulfate
4. HOH , which is water
5. sodium acetate
6. 180.16

Strength of Acids and Bases

Reading Guide

What You'll Learn

- **Determine** what is responsible for the strength of an acid or a base.
- **Compare and contrast** strength and concentration.
- **Examine** the relationship between pH and acid or base strength.
- **Examine** electrical conductivity.

Why It's Important

Understanding the strength of acids and bases helps you use them safely.

Review Vocabulary

acid strength: the ability of an acid to dissociate completely

New Vocabulary

- strong acid
- weak acid
- strong base
- weak base
- pH

FCAT Vocabulary

Strong and Weak Acids and Bases

Some acids must be handled with great care. For example, sulfuric acid found in car batteries can burn your skin, yet you drink acids such as citric acid in orange juice. Obviously, some acids are stronger than others. One measure of acid strength is the ability to dissociate in solution.

The strength of an acid or base depends on how many acid or base particles dissociate into ions in water. When a **strong acid** dissolves in water, almost 100 percent of the acid molecules dissociate into ions. HCl, HNO₃, and H₂SO₄ are examples of strong acids. When a **weak acid** dissolves in water, only a small fraction of the acid molecules dissociates into ions. Acetic acid and carbonic acid are examples of weak acids.

Ions in solution can conduct an electric current are called electrolytes. The more ions a solution contains, the more current it can conduct. The ability of a solution to conduct a current can be demonstrated using a lightbulb connected to a battery with leads placed in the solution, as shown in **Figure 17**. The strong acid solution conducts more current. The weak acid solution does not conduct as much current as a strong acid solution.

Figure 17 HCl is a strong acid. The bulb burns brightly. Acetic acid is a weak acid. The bulb is dimmer.

Tie to Prior Knowledge

Acid Strength Ask students to name acids they have encountered that weren't harmful and acids that were. **Possible answers:** Fruit juices with weak acids are not harmful; battery acid is harmful. Tell students that in this section, they will learn why some acids are stronger than others. L2

Activate Background Knowledge Tell students that pH is a measurement to rate the strength of acids and bases, indicating "positive hydrogen ions" or "H⁺ ions." Tell them that swimming pool and spa owners must test their water to find out if it is too acidic or basic and then adjust the water with chemicals. Ask students why it is important to have the proper pH.

Fun Fact

Hydrochloric acid is essential for digestion and is secreted by the lining of the stomach in quantities of 1.2 to 1.5 L per day.

IDENTIFYING

Misconceptions

Strong Disconnect In connection with acid, the word *strong* means that the acid forms ions easily. Some students may confuse the concept, thinking it is a contradiction to use the word *strong* with something that comes apart easily.

Use Science Words

Word Usage Have students complete the following sentence: A _____ will ionize only to a small extent because its molecules have a strong hold on their H atoms. **weak acid** L1 ELL

Reading Strategy

Paired Reading Allow partners to read the text about strong and weak acids and bases. After reading, one partner should explain the reaction equation formula while showing the change in units on each side. The other partner should check the explanation with the text. Have students alternate roles as they read and explain the four paragraphs and equations.

Figure 18 You can have a dilute solution of a strong acid and a concentrated solution of a weak acid.

This shows a dilute solution of HCl.

This shows a concentrated solution of acetic acid.

Strong and Weak Acids Equations describing dissociation are written in two ways. In strong acids, such as HCl, nearly all the acid dissociates. This is shown by writing the equation using a single arrow pointing toward the ions that are formed.

Almost 100 percent of the particles in solution are H_3O^+ and Cl^- ions, and only a negligible number of HCl molecules are present.

Equations describing the dissociation of weak acids, such as acetic acid, are written using double arrows pointing in opposite directions. This means that only some of the CH_3COOH dissociates and the reaction does not go to completion.

In an acetic acid solution, most of the particles are CH_3COOH molecules, and only a few CH_3COO^- and H^+ ions are in solution.

Strong and Weak Bases Remember that many bases are ionic compounds that dissociate to produce ions when they dissolve. A **strong base** dissociates completely in solution. The following equation shows the dissociation of sodium hydroxide, a strong base.

The dissociation of ammonia, which is a weak base, is shown using double arrows to indicate that not all the ammonia dissociates. A **weak base** is one that does not dissociate completely.

Because ammonia produces only a few ions and most of the ammonia remains in the form of NH_3 , ammonia is a weak base.

Strength and Concentration Sometimes, when talking about acids and bases, the terms *strength* and *concentration* can be confused. The terms *strong* and *weak* are used to classify acids and bases. The terms refer to the ease with which an acid or base dissociates in solution. *Strong* acids and bases dissociate completely; *weak* acids and bases dissociate only partially. In contrast, the terms *dilute* and *concentrated* are used to indicate the concentration of a solution, which is the amount of acid or base dissolved in the solution. It is possible to have dilute solutions of strong acids and bases and concentrated solutions of weak acids and bases, as shown in **Figure 18**.

Differentiated Instruction

English-Language Learners The difference between ionization and dissociation is subtle. Review these terms by stressing that ionization happens when nonionic substances break apart, interact with water, and produce ions. Dissociation is the separation of ionic substances, such as a salt. Use a model to visually represent these concepts.

Teacher FYI

Logarithmic Value The value of pH is based on a logarithmic scale. Each unit increment is a tenfold change in hydrogen ion concentration. So, if one solution has a pH of 3 and another has a pH of 2, the second is 10 times more acidic than the first.

Figure 19 The pH scale helps classify solutions as acidic or basic.

pH of a Solution

If you have a swimming pool or keep tropical fish, you know that the pH of the water must be controlled. Also, many shampoo products claim to control pH, making them suitable for your type of hair. The **pH** of a solution is a measure of the concentration of H^+ ions in it. The greater the H^+ concentration is, the lower the pH is and the more acidic the solution is. The pH measures how acidic or basic a solution is. To indicate pH, a scale ranging from 0 to 14 has been devised, as shown in **Figure 19**.

Reading Check If a solution has a pH of 8.5, does it have more hydroxide ions or hydronium ions?

As the scale shows, solutions with a pH lower than 7 are described as acidic, and the lower the value is, the more acidic the solution is. Solutions with a pH greater than 7 are basic, and the higher the pH is, the more basic the solution is. A solution with a pH of exactly 7 indicates that the concentrations of H^+ ions and OH^- ions are equal. These solutions are considered neutral. Pure water at 25°C has a pH of 7.

One way to determine pH is by using indicator paper. This paper undergoes a color change in the presence of H_3O^+ ions and OH^- ions in solution. The final color of the pH paper is matched with colors in a chart to find the pH, as shown in **Figure 20**. Is this an accurate way to determine pH?

An instrument called a pH meter is another tool to determine the pH of a solution. This meter is operated by immersing the electrode in the solution to be tested and reading the dial. Small, battery-operated pH meters with digital readouts, as shown in **Figure 20**, are precise and convenient for use outside the laboratory when testing the pH of soils and streams.

Figure 20 The pH of a sample can be measured in several ways. Indicator paper gives an approximate value quickly, however, a pH meter is quick and more precise.

Activity

Measure pH Provide samples, other than those shown in **Figure 19**, with which students can measure pH using universal pH paper. Examples may include spoiled milk, lemon juice, soap solutions, and dissolved antacids.

L2 ELL LS Visual-Spatial

Quick Demo

Examine pH Changes

Materials indicator paper (litmus or universal), vinegar, milk of magnesia, pH meter

Estimated Time 20 minutes

Procedure Use litmus paper or universal indicator paper to show that vinegar has an acidic pH value. Then add a small amount of milk of magnesia to the vinegar. Check the pH again to see whether it has changed. As the milk of magnesia is added, OH^- is brought into the solution. OH^- ions react with the H_3O^+ ions, so the pH should rise. Continue adding milk of magnesia until this effect is noticed on the pH indicator. If one is available, do this demonstration with a pH meter.

L2 ELL LS Visual-Spatial

Discussion

Indicators and pH Ask students to think of a reason why someone would use an indicator paper instead of a pH meter to obtain a pH value. Indicator paper may be used when controlling costs is an issue. A box of indicator paper is less expensive than a pH meter.

Reading Check

Answer hydroxide ions

Differentiated Instruction

Challenge Have students write chemical equations that show HCO_3^- acting to neutralize the addition of OH^- ions and the addition of H^+ ions. This would show how one of the blood buffers works. $HCO_3^- + OH^- \rightarrow H_2O + CO_3^{2-}$; $HCO_3^- + H^+ \rightarrow H_2CO_3$ **L3**

LS Logical-Mathematical

Science Journal

Sour Milk Have students describe the changes in pH that occur in milk as it spoils. They may need to examine the process in a nutrition reference or biology source. Lactose, commonly called milk sugar, is changed through bacterial action into lactic acid. This change lowers the pH of the solution. **L2 LS Logical-Mathematical**

Reading Check

Answer Buffers are solutions containing ions that react with acids or bases to minimize their effects. This is important because our blood needs to maintain a pH of about 7.4.

Post Reading

Draw Conclusions Have students explain why symbols for elements and formulas are used to show chemical reactions. What actions do single arrows and double arrows indicate? Point out that people of all languages can understand the notations. How are letters in words and symbols similar?

Assess

DAILY INTERVENTION

Check for Understanding

Visual-Spatial Bring in a can of frozen orange juice and a gallon container. Explain to the students that the orange juice in the can is a concentrated form, then add water and explain that the orange juice is now diluted.

Reteach

Acid Strength Place a small piece of magnesium ribbon in two separate Petri dishes. In the first one, add a few drops of 1M HCl. In the second, add a few drops of acetic acid. **WARNING:** Wear goggles, an apron, and gloves when working with HCl. Ask which is a strong acid. The HCl is a strong acid because it reacts with magnesium to produce more hydrogen gas. [L2] [IS]

Visual-Spatial

1 mL concentrated HCl

1 L
Saltwater
solution

pH 7.4
↓
pH 2.0

1 mL concentrated HCl

1 L
Blood

pH 7.4
↓
pH 7.2

Figure 21 This experiment shows how well blood plasma acts as a buffer. Adding 1 mL of concentrated HCl to 1 L of saltwater solution changes the pH from 7.4 to 2.0. Adding the same amount of concentrated HCl to 1 L of blood plasma changes the pH from 7.4 to 7.2.

Blood pH

Your blood circulates

throughout your body carrying oxygen, removing carbon dioxide, and absorbing nutrients from food that you have eaten. In order to carry out its many functions properly, the pH of blood must remain between 7.0 and 7.8.

The main reason for this is that

some enzymes cannot work outside this pH range. An enzyme is a protein molecule that acts as a catalyst for many reactions in the body. Yet you can eat foods that are acidic without changing the pH of your blood. How can this be? The answer is that your blood contains compounds called buffers that enable small amounts of acids or bases to be absorbed without harmful effects.

Buffers are solutions containing ions that react with additional acids or bases to minimize their effects on pH. One buffer system in blood involves bicarbonate ions, HCO_3^- . Because of these buffer systems, small amounts of even concentrated acid will not change pH much, as shown in **Figure 21**. Buffers help keep your blood close to a nearly constant pH of 7.4.

Reading Check

What are buffers and how are they important for health?

section 4 review

Summary

Strong and Weak Acids and Bases

- When strong acids dissolve in water, nearly all the acid particles dissociate into ions. When weak acids dissolve in water, few particles dissociate.
- When strong bases dissolve in water, nearly all base particles dissociate. When weak bases dissolve, only a few particles dissociate.
- Ions in solution can conduct electricity.
- Strength refers to the ability of an acid or base to dissociate in water; concentration refers to how much acid or base is in solution.

pH of a Solution

- pH describes a substance as acidic or basic.
- Buffers are substances that minimize the effects of an acid or base on pH.

Self Check

1. **Describe** what determines the strength of an acid. A base?
2. **Explain** how to make a dilute solution of a strong acid.
3. **Explain** how electricity can be conducted by solutions.
4. **Describe** pH values of 9.1, 1.2, and 5.7 as basic, acidic, or very acidic.
5. **Think Critically** The proper pH range for a swimming pool is between 7.2 and 7.8. Some pools use two substances, NaHCO_3 and HCl, to maintain this range. How would you adjust the pH if you found it was 8.2? 6.9?

Applying Math

6. **Use Equations** To determine the difference in acid strength, calculate 10^n , where n = difference between pHs. How much more acidic is a solution of pH 2.4 than a solution of pH 4.4?

Assessment

Oral Sometimes soil pH must be changed to encourage plant growth. Ask students whether adding $\text{Ca}(\text{OH})_2$, sometimes referred to as slaked lime, would raise or lower the pH of soil. The OH^- ions released by $\text{Ca}(\text{OH})_2$ would raise the pH. Use PASC, p. 89. [L2]

section 4 review

1. The strength of an acid is determined by its ability to produce H^+ ions in solution. The strength of a base is determined by its ability to produce OH^- ions in solution.
2. You can dilute hydrochloric acid, a strong acid, by adding a small amount of acid to a much larger amount of water.
3. An ionic compound breaks into its ions, which conduct electricity.
4. 9.1—basic; 1.2—very acidic; 5.7—acidic

5. pH of 8.2—add HCl; pH of 6.9—add NaHCO_3
6. $4.4 - 2.4 = 2.0$
 $10^2 = 100$

Determining Acidity

The science of acids and bases is not practiced only in high-tech laboratories by degreed scientists. You can investigate the acidic concentrations of things in your own home using a simple homemade indicator solution.

Real-World Problem

How can you tell if a substance is a strong or weak acid?

Goal

■ **Determine** the relative concentrations of common acidic substances.

Materials

homemade cabbage indicator (indicates both acids and bases)
coffee filter
waxed paper
grease pencil or masking tape
teaspoons (3)
alum
cream of tartar
fruit preservative

Safety Precautions

Procedure

1. Use the grease pencil or masking tape and a pencil to label three areas on the waxed paper *alum*, *cream of tartar*, and *fruit preservative*. These areas should be about 8 cm apart.
2. Place approximately $\frac{1}{2}$ teaspoon of each of the three powders on the waxed paper where labeled. Use a separate teaspoon for each substance.

3. Cut three strips from the coffee filter, about 1 cm wide by 8 cm long.
4. Dip the end of one of the strips into the cabbage indicator solution, then lay the wet end on top of the alum.
5. Wet a second strip and lay it in on top of the cream of tartar.
6. Wet the third strip and lay on top of the fruit preservative.
7. Wait 5 min, then check the indicator strips and record your observations.

Conclude and Apply

1. **Determine** if all three substances were acids. Did the indicator strips turn a similar color?
2. **Explain** why each substance produced a different color.
3. **Propose** a possible rank of the concentrations.
4. **Predict** what you would have observed if you used sodium hydroxide instead of alum.

Communicating Your Data

Compare your results with other groups in the class. Discuss any differences in the results you obtained.

LAB 775

Assessment

Process This investigation indicated the relative concentration of several acids. Using these results, can you draw conclusions about the strength of the acids? **No reliable conclusion can be made.** Concentration and strength are independent of each other. [L2]

Communicating Your Data

Conduct a discussion of the results and possible differences in outcomes. [L2]

Real-World Problem

Purpose Students will test several substances and rank the relative acid concentration by the color of the indicator. [L2]

Process Skills Lab techniques, observe, sequence, draw conclusions.

Time Required 30 minutes

Procedure

Alternative Materials Other common acidic substances such as vinegar, catsup, soda pop

Safety Precautions Have students wash hands after the experiment.

Teaching Strategies

- Prepare the indicator ahead of class according to the following recipe. Fill a glass quart jar with uncooked purple cabbage leaves that have been torn into small pieces. Heat distilled water to boiling, then fill the jar with the cabbage. Allow to cool to room temperature. Pour the cooled cabbage solution through a tea strainer into a second container and discard the cabbage leaves.
- Acids turn this indicator red, bases turn it green.

Conclude and Apply

1. yes, shades of red
2. Each substance has a different acid concentration.
3. Actual rank (most concentrated to least) is fruit preservative, cream of tartar, alum. Students may rank least to most concentrated if they interpret the colors in reverse sequence.
4. Sodium hydroxide is a base, so the indicator would turn green. Students may indicate simply a different color.

 Real-World Problem

Purpose Students compare the solubility of a solute at various temperatures. [L2] [ELL]

Logical-Mathematical

Process Skills measure, use numbers, communicate, make and use graphs, make and use tables, infer

Time Required 40 minutes

 Procedure

Alternate Materials In addition to sugar, other solutes such as CuSO_4 (**WARNING: toxic**) or KBr could be used.

Safety Precautions Students should use test tube holders when handling hot test tubes. They should not stir solutions with a thermometer.

Teaching Strategy Keep the hot plate setting low so the temperature changes will be slow.

Tie to Prior Knowledge Remind students about dissolving sugar in hot tea versus cold tea.

Troubleshooting Experiment with making the copper stirrers before the lab. Coil the copper wire around a pencil and check to be sure the coil fits into the test tubes being used.

Goal

■ **Observe** the effects of temperature on the amount of solute that dissolves.

Materials

distilled water at room temperature
large test tubes
Celsius thermometer
table sugar
copper wire stirrer, bent into a spiral
test-tube holder
graduated cylinder (25-mL)
beaker (250-mL) with 150 mL of water
electric hot plate
test-tube rack
ring stand

Safety Precautions

WARNING: Do NOT touch the test tubes or hot-plate surface when hot plate is turned on or cooling down. When heating a solution in a test tube, keep it pointed away from yourself and others. Do NOT remove goggles until cleanup, including washing hands, is completed.

Saturated Solutions

 Real-World Problem

Two major factors to consider when you are dissolving a solute in water are temperature and the ratio of solute to solvent. What happens to a solution as the temperature changes? How does solubility change as temperature is increased? To be able to draw conclusions about the effect of temperature, you must keep other variables constant. For example, you must be sure to stir each solution in a similar manner.

 Procedure

1. Place 20 mL of distilled water in a test tube. Add 30 g of sugar.
2. Stir. Does the sugar dissolve?
3. If it dissolves completely, add another 5 g of sugar to the test tube. Does it dissolve?
4. Continue adding 5-g amounts of sugar until no more sugar dissolves.
5. Now place the beaker of water on the hot plate and hang the thermometer from the ring stand so that the bulb is immersed about halfway into the beaker, making sure it does not touch the sides or bottom. Record the starting temperature.

Alternative Inquiry Lab

Change Variables Make this Lab an Inquiry Lab by asking students what they think will happen if two or more different kinds of solutes are dissolved in a solvent? In other words, how will this experiment result if multiple solutes are dissolved in the water? Let the students investigate solutes of

their choosing with safety guidance from the teacher. Some students may want to go further and investigate solute solubility in different solvents. Have students record their alternative activities and results in their Science Journals. [L2]

Using Scientific Methods

- Using a test-tube holder, place the test tube into the water.
- Gradually increase the temperature of the hot plate while stirring the solution in the test tube, until all the sugar dissolves.
- Note the temperature at which this happens.
- Add another 5 g of sugar and continue. Note the temperature at which this additional sugar dissolves.
- Continue in this manner until you have at least four data points. Note the total amount of sugar that has dissolved. Record your data in the data table.

Analyze Your Data

- Graph** your results using a line graph. Plot grams of solute per 20 g of water on the y-axis and plot temperature on the x-axis.
- Interpret Data** Using your graph, estimate the solubility of sugar at 100°C and at 0°C, the boiling and freezing point of water, respectively.

Dissolving Sugar in Water

Temperature	Total Grams of Sugar Dissolved
20°C–25°C	about 40 g
30°C–35°C	about 45 g
50°C	about 50 g
55°C–60°C	about 55 g

Conclude and Apply

- Explain** how the saturation change as the temperature was increased.
- Compare** your results with the data in **Table 2**.

Communicating Your Data

Compare your results with those of other groups and discuss any differences noted. Why might these differences have occurred? For more help, refer to the **Science Skill Handbook**.

LAB 777

Assessment

Oral Have students explain how the relationship between saturation and temperature shown in this activity can be used in making candy. Large amounts of sugar may be dissolved at a very high temperature, then cooled quickly to form sugar crystals used in candy making. Students should also observe how stirring influences crystal size. Use **Performance Assessment in the Science Classroom**, p. 93. **L2**

Communicating Your Data

Keeping the temperature constant while observing possible saturation is difficult. It is easy to go beyond the saturation level without knowing it. If the temperature increases at different rates, results will be different.

Analyze Your Data

Expected Outcome At higher temperatures, more sugar will dissolve.

Answers to Questions

- Check student graphs against their results for accuracy.
- approximately 98 g per 20 mL at 100°C and 35.8 g per 20 mL at 0°C

Error Analysis It may be difficult to tell whether the solute is dissolved when the solution is near saturation. Be sure students pause at each temperature long enough to give the solute time to dissolve. Otherwise, the amount of solute may be less than expected for saturation.

Conclude and Apply

- The amount of solute needed to cause saturation was greater with increasing temperature steps.
- Answers will vary.

Content Background

Acid rain is caused by water falling through polluted air. A number of factors determine the severity of the effects of acid rain. Among them are the amount and type of chemicals contained in the clouds and the contours and composition of the soil on which it falls. For example, soils formed over limestone or chalk can tolerate much higher levels of acid than those based on granite or sandstone. The alkalinity of limestone and chalk neutralizes acids before they can have a corrosive effect. Quartzite granite does not react with the acids, leaving them in the soil to be washed into streams and lakes. There is some disagreement over the extent of the harm caused by acid rain, but not over the fact that it is harmful.

Activity

Place a clean glass container in a safe place outside prior to an expected rainstorm. Collect a rain sample and check the pH using pH paper. Have students find the position of the pH of rainwater on the chart in Figure 19. **L2** **KS** Kinesthetic

Investigate the Issue

Research the patterns of acid rain across the country and the presumed sources. Note them on a national map and use it to discuss how the local area is affected. Find out whether you are in an area of acid rainfall, a source area or both. **L2**

Acid Rain

Protecting Earth from the Damaging Effects
of Chemically Loaded Precipitation

Acid precipitation is rain, snow, or sleet that is more acidic than unpolluted precipitation. It's caused by the burning of fossil fuels, such as coal, oil, and natural gas. In the United States, most gasoline and electricity come from fossil fuels. People burn fossil fuels each time they drive a car, heat a building, or turn on a light.

Normally, raindrops pick up particles and natural chemicals in the air. When rain falls, it mixes with the carbon dioxide in the atmosphere, giving clean rain a slightly acidic pH of 5.6. Then, natural chemicals found in the air and soil balance out the acidity, giving most lakes and streams a pH between 6.0 and 8.0. But when pollutants are introduced, these natural bases are not strong enough to neutralize these solutions. Wind can carry this acidic moisture for hundreds of miles before it falls to Earth as acid rain.

Eating Away at History

Like all acids, acid rain can corrode, or eat away at, substances. Many historical monuments, such as the Mayan temples in Mexico and the Parthenon in Greece, have been slowly but steadily damaged by acid rain. This kind of damage can be fixed, though it costs billions of dollars to ensure that ancient monuments and buildings are not destroyed.

Some Solutions

In some countries, high acid levels in lakes and streams have been lowered by adding lime to the water. Lime, a natural base, balances out the damaging chemicals. In the United States, all new cars must have catalytic converters, which help reduce the amount of exhaust pollution that vehicles give off.

You also can make a difference. Turning off the lights when you are not using them means a power plant does not have to produce as much electricity. By carpooling, using public transportation, and walking, there is less pollution from cars. The results of all these individual actions can make a huge difference in preserving our environment.

Ride a bike! It saves fuel, is nonpolluting, and helps preserve the environment.

List Go to a local park or forest. List any effects of acid rain that you see. Make a list of the things you do that use energy or cause pollution. Think about what your family can do to reduce pollution and save energy. Share your list with an adult.

TIME

For more information, visit
fl.gpescience.com

List If your local park shows symptoms of acid rain, try to determine the source of the acid rain. In many cases, the sources of acid rain are also major contributors to the local economy. Find out if the economic activity of your community produces acid rain-causing pollutants and what steps local industries and government have taken to address the problem. **L3**

Resources for Teachers and Students

Acid Rain, Sally Morgan, Franklin Watts: New York, 1999

Acid Rain, Louise Petheram, Bridgestone Books, Mankato, MN, 2003

Reviewing Main Ideas

Section 1 How Solutions Form

1. A solution is a mixture that has the same composition, color, density, and taste throughout.
2. The substance being dissolved is called a solute, and the substance that does the dissolving is called a solvent.
3. The rate of dissolving can be increased by stirring, increasing surface area, or increasing temperature.
4. Under similar conditions, small particles of solute dissolve faster than large particles.

Section 2 Solubility and Concentration

1. Some compounds are more soluble than others, and this can be measured.
2. *Concentrated* and *dilute* are not precise terms used to describe concentrations of solutions.
3. Concentrations can be expressed as percent by volume.
4. An unsaturated solution can dissolve more solute, while a saturated solution, such as this tea, cannot. A supersaturated solution is made by raising the temperature of a saturated solution and adding more solute. If it is cooled carefully, the supersaturated solution will retain the dissolved solute.

Section 3 Acids, Bases, and Salts

1. An acid is a substance that produces hydrogen ions, H^+ , in solution. A base produces hydroxide ions, OH^- , in solution.
2. Most foods can be classified as acidic or basic. Properties of acids and bases are due, in part, to the presence of the H^+ and OH^- ions.

3. Salts form when negative ions from an acid combine with positive ions from a base.
4. Dissociation is the process where an ionic solid separates into its positive and negative ions.

Section 4 Strength of Acids and Bases

1. The strength of an acid or base is determined by how completely it forms ions when it is in solution.
2. Strength and concentration are not the same thing. Concentration involves the relative amounts of solvent and solute in a solution, whereas strength is related to the extent to which a substance dissociates.

Assessment

Assessment Solutions

Directions: Carefully review the table and answer the following questions.

Composition of Common Solutions	
Solution	Created by combining
Brass	Solid-solid
Salt water	Solid-liquid
Vinegar	Liquid-liquid
Soda	Gas-liquid
Air	Gas-gas

1. According to the information in the table, ____.

A. solutions are always liquid in form
 B. solutions are always gases
 C. solutions are always liquids or gases
 D. solutions can be solid, liquid, or gas

2. According to the table, vinegar is created by combining ____.

F. liquids
 G. solids
 H. solids with gases
 I. liquids with gases

3. For the examples in the table, the solutions consisting of a liquid combined with either a gas or a solid are ____.

A. solids
 B. liquids
 C. gases
 D. water

L2

* FCAT Vocabulary

Fill in the vocabulary word(s) that correctly completes each sentence.

1. In lemonade, sugar is the _____ and water is the _____.
2. A(n) _____ is a substance that produces hydrogen ions, H^+ , in solution.
3. Adding a seed crystal may cause solute to crystallize from a(n) _____.
4. A(n) _____ produces hydroxide ions, OH^- , in solution.
5. If more of substance B dissolves in water than substance A, then substance B has a higher _____ than substance A.
6. When a(n) _____ dissolves in water, nearly all the acid molecules dissociate into ions.
7. The measure of the concentration of H^+ ions in solution is called the _____.
8. A solution in which water is the solvent is called a(n) _____ solution.

Checking Concepts

Choose the word or phrase that best answers the question.

9. What term is **NOT** appropriate to use when describing solutions?
A) gaseous C) liquid
B) heterogeneous D) solid

10. What is another name for sodium hydroxide (NaOH)?
A) ammonia C) lye
B) caustic lime D) milk of magnesia
11. When iodine is dissolved in alcohol, what term is used to describe the alcohol?
A) alloy C) solution
B) solvent D) solute
12. What word is used to describe a solution that is 85 percent copper and 15 percent tin?
A) alloy C) saturated
B) solvent D) solute
13. What is a common name for hydrochloric acid?
A) battery acid C) muriatic acid
B) citric acid D) vinegar
14. Which acid ionizes only partially in water?
A) HCl C) HNO_3
B) H_2SO_4 D) CH_3COOH
15. Carrots have a pH of 5.0. How would you describe them?
A) acidic C) an indicator
B) basic D) neutral
16. What is the pH of pure water at 25°C?
A) 0 C) 7
B) 5 D) 14
17. What can you increase to make a gas more soluble in a liquid?
A) particle size C) stirring
B) pressure D) temperature
18. If a solute crystallizes out of a solution when a seed crystal is added, what kind of solution is it?
A) dilute C) supersaturated
B) saturated D) unsaturated

Interpreting Graphics

Use the table below to answer question 19.

19. Explain which substance listed in the table would be most effective for neutralizing battery acid.

pH Readings

Substance	pH
Battery acid	1.5
Lemon juice	2.5
Apple	3
Milk	6.7
Seawater	8.5
Ammonia	12

Use the table below to answer question 20.

Limits of Solubility

Compound	Type of Solution	Solubility in 100 g Water at 20°C
CuSO_4	saturated	32.0 g
KCl	supersaturated	38.0 g
KNO_3	saturated	31.6 g
NaClO_3	unsaturated	45.8 g

20. **Identify** Using the data in Table 2, complete the table. Use the terms *saturated*, *unsaturated*, and *supersaturated* to describe the type of solution.

Thinking Critically

- Describe what happens to hydrogen chloride, HCl, when it is dissolved in water to form hydrochloric acid.
- Explain why ammonia is considered a base, even though it contains no hydroxide ions. Is it a strong or weak base?
- Explain why a concentrated acid is not necessarily a strong acid.
- Compare and Contrast** How would the pH of a dilute solution of HCl compare with the pH of a concentrated solution of the same acid?

25. Explain why the statement, "Water is the solvent in a solution," is not always true.

Applying Math

26. **Use Proportions** To make an indicator solution, a student mixes 3 mL of a concentrated solution with 97 mL of water. How much concentrate is needed to make 3 L of the indicator?

Use the graph below to answer question 27.

Temperature Effects on Solubility

- Interpret Data** Determine the temperature at which a solution of 80 g of potassium nitrate (KNO_3) in 100 mL of water is saturated.
- Measure in SI** You dissolve 153 g of potassium nitrate in enough water to make 1 L of solution. Then, you use a graduated cylinder to measure 80 mL of solution. What mass of potassium nitrate is in the 80-mL sample?
- Use Numbers** How would you make a 25-percent solution by volume of an apple-juice drink?

Thinking Critically

- Water interacts forming H_3O^+ and Cl^- ions in the dissociation process.
- Ammonia can accept H^+ ions from water, forming NH_4^+ ions and thus producing OH^- in water. It is a weak base.
- A concentrated acid has a large amount of acid dissolved in a solution. A strong acid easily donates H^+ ions. A concentrated acid could be a large amount of weak acid in a solution.
- A concentrated solution of HCl has a low pH. A dilute solution has a higher pH that is still below 7.
- Water can be the solute in a solution. For example, water may be dissolved in alcohol.

Applying Math

Math Standards

National: 1, 2, 9

Florida: MA.B.1.4.3, MA.F.1.1.1, MA.B.2.4.1, MA.A.3.4.1

- 90 mL
- 50°C
- $153 \text{ g} / 1000 \text{ mL} \times 80.0 \text{ mL} = 12.2 \text{ g KNO}_3$ [Please stack fraction. This is a pick up of answer #23 from ch 615]
- Place 25 mL of concentrated apple juice in 75 mL of water.

Standardized Test Practice Answer Sheet

Multiple Choice

1. A. 1000 B. 100 C. 10 D. 1

2. A. 1000 B. 100 C. 10 D. 1

3. A. 1000 B. 100 C. 10 D. 1

4. A. 1000 B. 100 C. 10 D. 1

5. A. 1000 B. 100 C. 10 D. 1

6. A. 1000 B. 100 C. 10 D. 1

7. A. 1000 B. 100 C. 10 D. 1

Gridded Response

	1	2	3	4	5
A	1	2	3	4	5
B	6	7	8	9	10
C	11	12	13	14	15
D	16	17	18	19	20
E	21	22	23	24	25

	1	2	3	4	5
A	1	2	3	4	5
B	6	7	8	9	10
C	11	12	13	14	15
D	16	17	18	19	20
E	21	22	23	24	25

60.02

Short Response

1. D
2. D
3. B
4. C
5. A

Gridded Response

6. 32 g
7. 0.10

Record your answers on the answer sheet provided by your teacher or on a sheet of paper.
The assessed Florida Benchmark appears above the question.

Multiple Choice

The graph below shows the solubility of various salts in water.

1. Which compound will make a saturated solution when added to 100 g of water?
- A. 20 g NaCl if the water is 50°C
 - B. 60 g of KNO_3 if the water is 100°C
 - C. 80 g NaClO_3 if the water is 30°C
 - D. 100 g KBr if the water is 90°C

2. A label on a flask reads 130 g KNO_3 /100 g of water. A thermometer reading shows a room temperature of 23°C . No crystals are seen on the bottom of the flask. How is this solution best described?

 - A. concentrated
 - B. dilute
 - C. saturated
 - D. supersaturated
3. What allows you to eat acidic foods without changing your blood pH?

 - A. blood plasma
 - B. buffers
 - C. enzymes
 - D. protein molecules
4. The following graph is a titration curve. The data indicate the changes that happened to the solution as drops of a strong base were added.

Acids, Bases, and Salts

At the instant of neutralization, what is in the beaker (besides water)?

- A.** acid only
B. base only
C. salt only
D. equal amounts of each

5. Which chemical formula below describes a hydronium ion?

A. H_3O^+
B. OH
C. COOH
D. H_2O

Gridded Response

6. The solubility of potassium chloride in water is 34 g per 100 g of water at 20°C . A warm solution containing 100 g of potassium chloride in 200 g of water is cooled to 20°C . How many grams of potassium chloride will come out of solution?
7. When the pH of a solution drops from 3.0 to 1.0, the hydronium ion concentration increases by a factor of 100 fold from 0.0010. What is the concentration at $\text{pH} = 1.0$?

Short Response

8. The drawing below shows carbon dioxide gas dissolved in water.

What are two ways you could make more gas dissolve in the water?

9. Name the salt that is produced by each of the following acid-base pairs.

Extended Response

10. One of the solutions has a pH of 10, the other pH of 12. In one beaker, the bulb glows more brightly than does the other.

Explain why the bulbs glow with different intensities. Use the words *strong* and *weak* in your answer.

11. You are given a clear water solution containing potassium nitrate. How could you determine whether the solution is unsaturated, saturated, or supersaturated?
12. Explain why a weak acid in solution has a higher pH than a strong acid of the same concentration.

Test-Taking Tip

Answer Bubbles Double-check that you are filling in the correct answer bubble for the question number you are working on.

Short Response

8. You could cool the liquid or increase the pressure of the carbon dioxide over the liquid.
9. sodium chloride; potassium nitrate; calcium sulfate

Extended Response

10. The base with the higher pH is a stronger base and therefore dissociates more completely than does the one with the lower pH. The stronger base releases more OH^- ions and conducts more electricity.
11. You could add a single crystal of potassium nitrate to the solution. If the crystal dissolved, the solution is unsaturated. If the crystal sank to the bottom, the solution is saturated. If, when the crystal is added, more potassium nitrate crystallizes out, the solution was supersaturated.
12. The pH of a weak acid is higher because a weak acid produces fewer H_3O^+ ions than a strong acid at the same concentration.

Rubrics

For more help evaluating Short- and Extended-Response questions, see the rubrics on p. 9T.

Section/Objectives	Standards		Labs/Features
Chapter Opener	National	State/Local	Launch Lab: The Size of a Nucleus, p. 785 Foldables, p. 785
	See pp. 16T–17T for a Key to Standards.		
Section 1 Radioactivity  1 session  .5 block 1. Describe the structure of an atom and its nucleus. 2. Explain what radioactivity is. 3. Compare and contrast properties of radioactive and stable nuclei. 4. Discuss the discovery of radioactivity.	National Content Standards: UCP.1, UCP.2, UCP.3, UCP.5, A.1, A.2, B.1, B.2, G.3	Florida Benchmarks: SC.A.2.4.1, SC.A.2.4.3, SC.B.1.4.2, SC.B.2.4.1, SC.C.2.4.4	MiniLAB: Modeling the Strong Force, p. 789 Science Online, p. 790
Section 2 Nuclear Decay  1 session  .5 block 5. Compare and contrast alpha, beta, and gamma radiation. 6. Define the half-life of a radioactive material. 7. Describe the process of radioactive dating.	National Content Standards: UCP.1, UCP.2, UCP.3, UCP.5, A.1, A.2, B.1, B.2	Florida Benchmarks: SC.A.2.4.3, SC.H.3.4.5	
Section 3 Detecting Radioactivity  2 sessions  1 block 8. Describe how radioactivity can be detected in cloud and bubble chambers. 9. Explain how an electroscope can be used to detect radiation. 10. Explain how a Geiger counter can measure nuclear radiation.	National Content Standards: UCP.1, UCP.2, UCP.3, UCP.5, A.1, A.2, B.1, B.2, F.1	Florida Benchmarks: SC.A.2.4.3	Applying Math: The Age of Rocks, p. 798 Integrate Social Studies, p. 799
Section 4 Nuclear Reactions  3 sessions  1.5 block 11. Explain nuclear fission and how it can begin a chain reaction. 12. Discuss how nuclear fusion occurs in the Sun. 13. Describe how radioactive tracers can be used to diagnose medical problems. 14. Discuss how nuclear reactions can help treat cancer.	National Content Standards: UCP.1, UCP.2, UCP.3, UCP.5, A.1, A.2, B.1, B.2, B.4, F.1, G.3	Florida Benchmarks: SC.A.2.4.3–4, SC.B.1.4.2, SC.B.2.4.1, SC.C.2.4.4, SC.H.1.4.1–3, SC.H.1.4.5, SC.H.1.4.7, SC.H.3.4.3, SC.H.3.4.5	MiniLAB: Modeling a Nuclear Reaction, p. 802 Science Online, p. 803 Integrate Chemistry, p. 804 Visualizing PET Scans, p. 805 Lab: Chain Reactions, p. 807  Video Lab Lab: Modeling Transmutations, pp. 808–809 Science and History: The Nuclear Alchemists, p. 810

Section Focus

Section Focus Transparency **Scientific Sacrifice** **Chapter 25**

Marie and Pierre Curie show here at their laboratory in Paris, France, helped pioneer the study of radioactivity. For seven years, husband and wife mined tons of material in search of the deadly radioactive elements uranium and polonium. The Curie's continued their research. Much of today's nuclear science is based on their work.

1. Uranium and radium are described as being 'deadly'. What do you think they released that makes them so dangerous?

Name _____

L2

Section Focus Transparency **A Distant Relative** **Chapter 25**

In 1934, Lise Meitner and Otto Hahn discovered the nuclear fission of the world's heaviest element, uranium. Lise Meitner and Otto Hahn were awarded the Nobel Prize for their discovery. Lise Meitner was a Jewish woman, and she was forced to flee Germany in 1938. She was later recognized for her work on the discovery of nuclear fission.

1. If radioactive material is said to decay, from the general meaning, of, for or what does this indicate?

Where was the radioactive material that was exposed to date, Lucy?

Every radioactive isotope has a half-life. What does this mean?

L2

Section Focus Transparency **Home Safety** **Chapter 25**

Radiation is a natural part of our environment. It is found in the air, in the ground, and in the food we eat. However, it can also be found in the home. Radon gas is a natural byproduct of the decay of uranium and thorium. It is a colorless, odorless gas that can accumulate in homes. Radon is a leading cause of lung cancer. It is important to test for radon in homes and to take steps to reduce radon levels if necessary.

1. How can radon be detected? How does it affect the body?

What is the role of radon in the environment?

1. Explain the natural source of radon in the home. What steps can be taken to reduce radon levels?

L2

Section Focus Transparency **PET Scan** **Chapter 25**

Positron emission tomography (PET) scans are used to detect and measure metabolic activity in the body. They are used to diagnose and monitor various conditions, including cancer. PET scans work by injecting a small amount of a radioactive tracer into the body. The tracer emits positrons, which interact with electrons in the body to produce gamma rays. These rays are detected by a PET scanner, which creates a 3D image of the body's internal structures.

1. What part of the body is being imaged? How does it work?

2. Describe the role of the PET scanner in the diagnosis of cancer.

L2

This is a representation of key blackline masters available in the Teacher Classroom Resources. See Resource Manager boxes within the chapter for additional information.

Assessment

Assessment Transparency **Nuclear Changes** **Chapter 25**

Elements

Element name	Number of protons	Number of neutrons
Carbon	6	6
Cobalt	27	34
Iodine	53	78
Uranium	92	146

Isotopes

Isotope name	Number of protons	Number of neutrons
Carbon-14	6	8
Cobalt-60	27	33
Iodine-131	53	78
Uranium-235	92	143

1. The element carbon has at least one other isotope, carbon-14. Accountable for the difference in the number of neutrons in this isotope.

2. What is the difference between isotopes?

3. What do the elements and their isotopes have in common?

4. What is the difference between isotopes?

5. What is the difference between isotopes?

L2

Key to Teaching Strategies

The following designations will help you decide which activities are appropriate for your students.

- L1** Level 1 activities should be appropriate for students with learning difficulties.
- L2** Level 2 activities should be within the ability range of all students.
- L3** Level 3 activities are designed for above-average students.
- ELL** ELL activities should be within the ability range of English Language Learners.

COOP LEARN Cooperative Learning activities are designed for small group work.

MS Multiple Learning Styles logos, as described on page 12T, are used throughout to indicate strategies that address different learning styles.

P These strategies represent student products that can be placed into a best-work portfolio.

PBL Problem-Based Learning activities apply real-world situations to learning.

Science Content Background

section 1 Radioactivity

The Nucleus

There are six “flavors” of quarks—the fundamental components of matter. The up, charm, and top quarks have a charge of $+2/3$. The down, strange, and bottom quarks have a charge of $-1/3$. Protons are made of two up quarks and one down quark. Neutrons are made of one up quark and two down quarks. Quarks are bound tightly together by the strong force so they are not observed as free particles.

In periodic tables, the atomic mass of an element usually is not written as a whole number. For example, silicon is shown as having an atomic mass of 28.086. The atomic mass on the periodic table is the average of the masses of all the isotopes of an element weighted by the relative occurrence of each isotope.

Carbon is the standard for the atomic mass of elements. It is defined as having a mass of 12 atomic mass units.

Discovery of Radioactivity

Initial investigators of radioactivity were not aware of the long-term health risks associated

B. Daemmrich/The Image Works

with the handling of radioactive materials. Unfortunately this may have contributed to the death of Marie Curie due to leukemia in 1934.

section 2 Nuclear Decay

Gamma Rays

Gamma rays penetrate human tissue. Some cellular necrosis is not a problem as most cells can be replaced. The larger threat is from gamma rays that pass through tissues and change DNA. These changes can make a cell function less efficiently. When the cell reproduces, it produces more cells with less than optimal functioning. Aging is caused by the buildup of these kinds of cells. In rarer circumstances, DNA is damaged in a way that results in a malfunction in the control of the growth of the cell, resulting in rapid cell growth and division—a condition known as cancer.

Teacher to Teacher

Cindy L. Marr

"Use coated candies to simulate radioactive decay. Pour 60–100 candies on a paper plate. Each candy represents a radioactive atom. Candies with letters showing are "radioactive," and the others have "decayed." Count the radioactive atoms, record the number in a data table, and then remove the decayed atoms. Pour the remaining candies on the plate again. Repeat the procedure until all the "atoms" have "decayed." Plot the data (atoms left v. trial number) and draw a smooth curve through the points. Obtain the half-life by selecting two values on the y-axis, one twice as large as the other, and finding the difference between corresponding values on the x-axis."

Cindy Marr

Putting food into sealed bags and exposing it to gamma rays can reduce the need for chemical preservatives or canning procedures. However, many people object to food irradiation. Some believe it will make food radioactive, which is not true. Others are concerned with the effects of eating foods that have been exposed to ionizing radiation.

Section 3 Detecting Radioactivity

Measuring Radiation

Many radiation detectors use the tendency of radiation to ionize atoms as a means for detection. Ionization can be as simple as knocking an electron off an atom or it might involve the more complex breakup of a molecule into positive and negative pieces.

Health care workers who use X rays and people who work with radioactivity often wear radiation badges and carry pocket dosimeters.

The badges are worn for periods of one to three months and then analyzed to assess how much radiation the person has received during that period. Pocket dosimeters tell the wearer how much radiation he or she has received in a shorter time period, such as one day of work.

Background Radiation

Cosmic radiation in space is an obstacle that must be overcome before astronauts can spend longer periods in space. The majority of cosmic rays are protons, but heavier nuclei are common. Some cosmic rays are gamma rays.

Section 4 Nuclear Reactions

Nuclear Fusion

Research is under way to develop reactors that use nuclear fusion to generate electricity. Unlike fission reactors, a fusion reactor would generate very little long-lived radioactive material. However, extremely high temperatures are needed for the fusion reactions to occur and the plasma created is difficult to confine under these conditions. One way to contain the plasma is to use strong magnetic fields that prevent the plasma from touching the inside surfaces of the reactor.

Planet Power

Although less than one billionth of the energy emitted by the Sun falls on Earth, the energy Earth receives from the Sun powers the entire planet. Without the Sun's energy, life on Earth could not exist. This energy is produced inside the Sun by nuclear fusion—a nuclear reaction in which atomic nuclei join together.

Science Journal In your Science Journal, write a paragraph describing your impressions of the Sun.

784

Theme Connection

Stability and Change Although the nucleus of an atom is stable during normal chemical reactions, it undergoes profound changes during nuclear reactions. These can be so profound that they change the identity of the element.

About the Photo

The Sun This is a photograph of the Sun, which is composed mostly of hydrogen. The enormous amount of energy emitted by the Sun comes from nuclear fusion, in which hydrogen atoms fuse into helium atoms, releasing energy.

Start-Up Activities

The Size of a Nucleus

Do you realize you are made up mostly of empty space? Your body is made of atoms, and atoms are made of electrons whizzing around a small nucleus of protons and neutrons. The size of an atom is the size of the space in which the electrons move around the nucleus. In this lab, you'll find out how the size of an atom compares with the size of a nucleus.

1. Pour several grains of sugar onto a sheet of dark paper.

2. Choose one of the grains of sugar to represent the nucleus of an atom. Tape this grain to the center of the sheet of paper.

3. Place the sheet of paper in a large open space.

4. Use a meterstick to measure a distance of 10 m from the sugar grain. This distance represents the radius of the electron cloud around an atom.

5. **Think Critically** In your Science Journal, compare the size of an atom to the size of a nucleus. If an electron is much smaller than a nucleus, explain why an atom contains mostly empty space.

FOLDABLES™ Study Organizer

Radioactivity and Nuclear Reactions Make the following Foldable to help you understand radioactivity and nuclear reactions.

STEP 1 Fold a sheet of paper in half lengthwise.

STEP 2 Fold paper down 2.5 cm from the top. (Hint: From the tip of your index finger to your middle knuckle is about 2.5 cm.)

STEP 3 Open and draw lines along the 2.5-cm fold. Label as shown.

Summarize in a Table As you read the chapter, write what you learn about radioactivity in the left column and what you learn about nuclear reactions in the right column.

Purpose Use this Launch Lab to introduce students to what the interior of an atom is like.
Preparation Choose an outdoor location that will safely accommodate all the groups. To avoid confusion, assign a location for each group.

Materials meterstick, sugar, sheet of dark paper

Teaching Strategies Ask one student to be a group leader and assign the tasks of choosing and measuring the sugar grain and measuring the 10-m distance to group members.

Think Critically

The space in which the electrons move is much larger than the nucleus. Since the electron is much smaller than the nucleus, the space occupied by the electrons and the nucleus is much smaller than the space occupied by the atom.

Assessment

Content Sometimes it is said that an atom is mostly empty space. Ask students to write a paragraph discussing whether this statement is true. The sizes of the nucleus and electrons in an atom are much smaller than the size of the atom. However, electrons move throughout the space occupied by the atom. Use **Performance Assessment in the Science Classroom**, p. 89.

Scientific Sacrifice

Chapter 25

Pierre and Marie Curie, shown here in their laboratory in Paris, France, helped pioneer the study of radioactivity. For years they handled and examined uranium and radium, unaware of the death hazards. Even with deteriorating health, the Curies continued their research. Much of today's nuclear science is based on their work.

- Uranium and radium are always decaying. What do you think they release that makes them so dangerous?
- Name some present day uses of uranium.

L2

Reading Guide

What You'll Learn

- Describe the structure of an atom and its nucleus.
- Explain what radioactivity is.
- Compare and contrast properties of radioactive and stable nuclei.
- Discuss the discovery of radioactivity.

Why It's Important

Radioactivity is everywhere because every element on the periodic table has some atomic nuclei that are radioactive.

Review Vocabulary

long-range force: a force that becomes weaker with distance, but never vanishes

New Vocabulary

- strong force
- radioactivity

The Nucleus

Every second you are being bombarded by energetic particles. Some of these particles come from unstable atoms in soil, rocks, and the atmosphere. What types of atoms are unstable? What type of particles do unstable atoms emit? The answers to these questions begin with the nucleus of an atom.

Recall that atoms are composed of protons, neutrons, and electrons. The nucleus of an atom contains the protons, which have a positive charge, and neutrons, which have no electric charge. The total amount of charge in a nucleus is determined by the number of protons, which also is called the atomic number. You might remember that an electron has a charge that is equal but opposite to a proton's charge. Atoms usually contain the same number of protons as electrons. Negatively charged electrons are electrically attracted to the positively charged nucleus and swarm around it.

Protons and Neutrons in the Nucleus Protons and neutrons are packed together tightly in a nucleus. The region outside the nucleus in which the electrons are located is large compared to the size of the nucleus. As **Figure 1** shows, the nucleus occupies only a tiny fraction of the space in the atom. If an atom were enlarged so that it was 1 km in diameter, its nucleus would have a diameter of only a few centimeters. But the nucleus contains almost all the mass of the atom, because the mass of one proton or neutron is almost 2,000 times greater than the mass of an electron.

Figure 1 The size of a nucleus in an atom can be compared to a marble sitting in the middle of an empty football stadium.

Reading Preview

Tie to Prior Knowledge

Parts of an Atom Ask students to recall the parts of an atom. Students are probably aware that an atom is composed of electrons swirling around a nucleus of protons and neutrons. In this section they will learn about the force that holds the nucleus together and why some nuclei are radioactive.

Vocabulary Usage Use the new vocabulary words in sentences. Then ask students to predict meaning. Have them check the meaning in the text to validate or modify predictions.

Figure 2 The particles in the nucleus are attracted to each other by the strong force.

The Strong Force

How do you suppose protons and neutrons are held together so tightly in the nucleus? Positive electric charges repel each other, so why don't the protons in a nucleus push each other away? Another force, called the **strong force**, causes protons and neutrons to be attracted to each other, as shown in **Figure 2**.

The strong force is one of the four basic forces in nature and is about 100 times stronger than the electric force. The attractive forces between all the protons and neutrons in a nucleus keep the nucleus together. However, protons and neutrons have to be close together, like they are in the nucleus, to be attracted by the strong force. The strong force is a short-range force that quickly becomes extremely weak as protons and neutrons get farther apart. The electric force is a long-range force, so protons that are far apart still are repelled by the electric force, as shown in **Figure 3**.

Reading Check What causes the attraction between protons and neutrons?

Figure 3 The total force between two protons depends on how far apart they are. **Infer** whether the total force between two protons could become zero.

When protons are close together, they are attracted to each other. The attraction due to the short-range strong force is much stronger than the repulsion due to the long-range electric force.

When protons are too far apart to be attracted by the strong force, they still are repelled by the electric force between them. Then the total force between them is repulsive.

SECTION 1 Radioactivity 787

Teacher FYI

Four Fundamental Forces Scientists have identified four fundamental forces of nature. The strong force holds neutrons and protons together; the electromagnetic force acts

between particles with electric charge; the weak force is involved in the neutron decay process; and the weakest force is gravity.

2 Teach

Activity

Atomic Structure To review atomic structure, display a periodic table. Have students choose an element and draw its structure on the board using different colors for protons, neutrons, and electrons. Tell students that physicists often refer to the number of protons (atomic number) as "Z." **L1**

ELL **AS** Visual-Spatial

Make a Model

The Nucleus The strong force is significant only for a distance that is less than the width of a few protons and neutrons. Have students model the nucleus of a nitrogen atom by drawing closely packed circles as nucleons. (Tracing around a penny works well.) Students should draw seven neutrons and seven protons, randomly placed and colored differently. By multiplying the diameter of a circle by three, they can see about how far the strong force can be felt. **L2**

ELL **AS** Kinesthetic **P**

Reading Check

Answer the strong force

Caption Answer

Figure 3 Yes, if they were separated by a distance such that the attractive strong force was balanced by the repulsive electric force.

Reading Strategy

Directed Reading Have students skim the text prior to reading. They should note titles, figures, and bold print. Ask them to predict what they will learn and write their predictions in their Science Journals. Have students check off or modify their prediction statements as they read.

Visual Learning

Figure 4 Point out to students that in the large nucleus the protons near the center of the nucleus feel a slightly greater strong force than those near the edge of the nucleus. Protons near the edge have no neighbors on the outer side of the nucleus to pull on them. This can be a source of instability in the nucleus. **L2** **IS** **Visual-Spatial**

Quick Demo

Strong Force v. Magnetism

Materials magnets

Estimated Time 2–5 minutes

Procedure Use magnets to review the concepts of repulsion and attraction. With magnetism, like poles repel and unlike poles attract. Similarly, two protons (both positively charged) repel each other. With the strong force, however, the charge doesn't matter; all protons and neutrons attract one another at very short distances. **L2** **ELL** **IS** **Visual-Spatial**

Discussion

Periodic End Why is there an end to the periodic table? As the number of protons in the nucleus increases, the relative effect of the electromagnetic repulsion between protons increases, causing large nuclei to be unstable. Beyond a certain point, the electromagnetic repulsion makes large nuclei too unstable to exist. **L3** **IS** **Logical-Mathematical**

IDENTIFYING

Misconceptions

Radioactive Energy Students may think that radioactive materials glow. Explain that energy is given off, but not in the form of light. Radiation can, however, induce fluorescence in some materials.

A

B

Figure 4 Protons and neutrons are held together less tightly in large nuclei. The circle shows the range of the attractive strong force. **A** Small nuclei have few protons, so the repulsive force on a proton due to the other protons is small. **B** In large nuclei, the attractive strong force is exerted only by the nearest neighbors, but all the protons exert repulsive forces. The total repulsive force is large.

Attraction and Repulsion Some atoms, such as uranium, have many protons and neutrons in their nuclei. These nuclei are held together less tightly than nuclei containing only a few protons and neutrons. To understand this, look at **Figure 4A**. If a nucleus has only a few protons and neutrons, they are all close enough together to be attracted to each other by the strong force. Because only a few protons are in the nucleus, the total electric force causing protons to repel each other is small. As a result, the overall force between the protons and the neutrons attracts the particles to each other.

Forces in a Large Nucleus However, if nuclei have many protons and neutrons, each proton or neutron is attracted to only a few neighbors by the strong force, as shown in **Figure 4B**. The other protons and neutrons are too far away. Because only the closest protons and neutrons attract each other in a large nucleus, the strong force holding them together is about the same as in a small nucleus. However, all the protons in a

large nucleus exert a repulsive electric force on each other. Thus, the electric repulsive force on a proton in a large nucleus is larger than it would be in a small nucleus. Because the repulsive force increases in a large nucleus while the attractive force on each proton or neutron remains about the same, protons and neutrons are held together less tightly in a large nucleus.

Radioactivity

Many types of nuclei are held together permanently and are stable. However, there are many other types of nuclei that are unstable. These nuclei break apart, or decay, by emitting particles and energy. This process of nuclear decay is called **radioactivity**. A nucleus that decays is called a radioactive nucleus.

Nuclei that contain large numbers of protons and neutrons tend to be unstable. In fact, all nuclei that contain more than 83 protons are radioactive. However, many other nuclei that contain fewer than 83 protons also are radioactive. Even some nuclei with only one or a few protons are radioactive.

Almost all elements with more than 92 protons don't exist naturally on Earth. They have been produced only in laboratories and are called synthetic elements. These synthetic elements are unstable and decay soon after they are created.

Cultural Diversity

Hideki Yukawa In 1949 Japanese scientist Hideki Yukawa received the Nobel Prize in physics for his work on nuclear forces. In 1935 he predicted the existence of particles he called mesons, that would transfer energy between protons and neutrons and hold the nucleus together. His theory

also stated that the nuclear force must be stronger than electromagnetic forces over short distances in order to overcome the repulsion between protons. The mesons Yukawa predicted, now known as pions, were discovered in 1937.

Converting Mass into Energy When an unstable nucleus decays, energy is emitted. If energy is conserved and cannot be created or destroyed, where does this energy come from? Recall that in nuclear reactions, mass can be converted into energy. As an unstable nucleus decays, a small amount of mass is converted into energy. As a result, the mass of the initial nucleus is slightly larger than the mass of the final nucleus plus the mass of any particles that are emitted. A large amount of energy is produced by the conversion of only a small amount of mass.

Isotopes The atoms of an element all have the same number of protons in their nuclei. For example, the nuclei of all carbon atoms contain six protons. However, naturally occurring carbon nuclei can have six, seven, or eight neutrons. Nuclei that have the same number of protons but different numbers of neutrons are called isotopes. The element carbon has three isotopes that occur naturally. The atoms of all isotopes of an element have the same number of electrons and have the same chemical properties. **Figure 5** shows two isotopes of helium.

Nuclear Numbers A nucleus can be described by the number of protons and neutrons it contains. The number of protons in a nucleus is called the atomic number. Because the mass of all the protons and neutrons in a nucleus is nearly the same as the mass of the atom, the number of protons and neutrons is called the mass number.

Reading Check What is the atomic number of a nucleus?

A nucleus can be represented by a symbol that includes its atomic number, mass number, and the symbol of the element it belongs to. The symbol for the nucleus of the stable isotope of carbon is shown below as an example.

This isotope is called carbon-12. The number of neutrons in the nucleus is the mass number minus the atomic number. So the number of neutrons in the carbon-12 nucleus is $12 - 6 = 6$. Carbon-12 has six protons and six neutrons. Now, compare the isotope carbon-12 to this radioactive isotope of carbon:

The radioactive isotope is carbon-14. How many neutrons does carbon-14 have?

Figure 5 These two isotopes of helium each have the same number of protons, but different numbers of neutrons.

Identify the ratio of protons to neutrons in each of these isotopes of helium.

Modeling the Strong Force

Procedure

1. Gather 15 yellow candies to represent neutrons and 13 red and 2 green candies to represent protons.
2. Model a small nucleus by placing 2 red protons and 3 neutrons around a green proton so they touch.
3. Model a larger nucleus by arranging the remaining candies around the other green proton so they are touching.

Analysis

1. Compare the number of protons and neutrons touching a green proton in both models.
2. Suppose the strong force on a green proton is due to protons and neutrons that touch it. Compare the strong force on a green proton in both models.

Caption Answers

Figure 5 Helium-3: 2 to 1, Helium-4: 2 to 2

Text Question Answer

8

Reading Check

Answer the number of protons

Purpose Students construct models to discover how the size of the nucleus affects the strong force on protons. **L2 LS**

Kinesthetic

Materials small candies (15 yellow, 13 red, two green)

Teaching Strategy Remind students that both green and red candies represent protons; the green candy is used to draw attention to a single proton in each model.

Analysis

1. About the same number touch the green proton in both models.
2. The strong force on the green proton is the same in each model. The electromagnetic force, however, would increase in the larger nucleus, making it less stable.

Assessment

Process Show students a drawing of a uranium nucleus and ask whether it is stable. **It is too large to be stable.** Use PASC, p. 89.

Differentiated Instruction

Challenge Have students determine the size of the nuclei of helium, neon, argon, krypton, xenon, radon, and uranium. Calculate the ratio of the diameter of each nucleus to its atomic mass and graph using the atomic mass on the x -axis and the ratio on the y -axis. Does the ratio remain constant as the size of the nucleus increases? Explain why this would be true. **L3**

Visually Impaired Allow visually impaired students to hold magnets and feel the attraction and repulsion to help them understand what happens when two protons are close together. Explain that the strong force is like your hands holding the repelling magnets close together.

Post Reading

Extended Research Radioactivity is used for sterilization, protecting works of art, and fire detectors. Have students research one of the many applications of radioactivity and create a written report. Students should present findings to the class.

Content Background

Marie Curie is credited with coining the term radioactivity in a paper written with Pierre in which they presented the discovery of polonium. Marie was the first person ever to receive two Nobel prizes. She shared the first in physics in 1903 with Pierre and Becquerel for their discovery of radioactivity. She received the second in 1911 in chemistry for her discovery and isolation of radium and polonium. (Pierre died in 1906, so he did not share in the chemistry prize.)

3 Assess

DAILY INTERVENTION

Check for Understanding

Logical-Mathematical Why don't elements with atomic numbers greater than 92 exist naturally on Earth in significant quantities? *because they are so unstable that if they are created, they decay almost immediately* [L3] [IS]

Reteach

Reviewing Isotopes Write on the board the chemical symbol, atomic mass, and atomic number of an isotope. Have students tell the number of protons and neutrons the element has and predict whether the isotope is radioactive. Do this for several isotopes. [L2]

[ELL] [IS] **Visual-Spatial**

Assessment

Content Have students work in groups to create games that teach about radioactive elements. Games should reinforce the concept that unstable nuclei cause radioactivity. Use **Performance Assessment in the Science Classroom**, p. 169.

Figure 6 The dark spots on this photographic plate were made by the radiation emitted by radioactive uranium atoms. Uranium salt had been placed next to the plate by Henri Becquerel in 1896.

The Discovery of Radioactivity

In 1896, Henri Becquerel left uranium salt in a desk drawer with a photographic plate. Later, when he developed the plate, shown in **Figure 6**, he found an outline of the clumps of the uranium salt. He hypothesized that the uranium salt had emitted some unknown invisible rays, or radiation, that had darkened the film.

Two years after Becquerel's discovery, Marie and Pierre Curie discovered two new elements, polonium and radium, that also were radioactive. To obtain a sample of radium large enough to be studied, they developed a process to extract radium from the mineral pitchblende. After more than three years, they were able to obtain about 0.1 g of radium from several tons of pitchblende. Years of additional processing gradually produced more radium that was made available to other researchers all over the world.

Activity Create a timeline showing important events in the life of Marie Curie.

section 1 review

Summary

The Strong Force

- The short-ranged strong force causes neutrons and protons to be attracted to each other.
- The long-ranged electric force causes protons to repel each other.
- The combination of the strong and electric forces causes protons and neutrons in a large nucleus to be held together less tightly than in a small nucleus.

Radioactivity and Isotopes

- Radioactivity is the process of nuclear decay.
- Isotopes of an element have the same number of protons, but different numbers of neutrons.
- The atomic number is the number of protons in a nucleus. The mass number is the number of protons and neutrons in a nucleus.

Self Check

1. **Describe** the properties of the strong force.
2. **Compare** the strong force between protons and neutrons in a small nucleus and a large nucleus.
3. **Explain** why large nuclei are unstable.
4. **Identify** the contributions of the three scientists who discovered the first radioactive elements.
5. **Think Critically** What is the ratio of protons to neutrons in lead-214? Explain whether you would expect this isotope to be radioactive or stable.

Applying Math

6. **Calculate a Ratio** What is the ratio of neutrons to protons in a nucleus of radon-222?
7. **Use Percentages** A silicon rod contains 30.21 g of silicon-28, 1.53 g of silicon-29, and 1.02 g of silicon-30. Calculate the percentage of each isotope in the rod.

section 1 review

1. short range, attractive, exists between protons, neutrons, and protons and neutrons
2. The strong force is exerted by nearest neighbors, so it is nearly the same in both nuclei.
3. Large nuclei have so many protons that the strong force is unable to overcome the total electrical repulsion.
4. Becquerel found that uranium salt emitted radiation. Marie and Pierre Curie discovered polonium and radium.
5. $82/132 = 0.62$; might be radioactive because the ratio of protons to neutrons differs from the 2-to-3 (0.67) ratio for stable heavy elements
6. $86/136 = 0.63$
7. total mass of rod = 32.76 g. Percentage of silicon-28 = $30.21/32.76 = 92.2\%$; silicon-29 = $1.53/32.76 = 4.7\%$; silicon-30 = $1.02/32.76 = 3.1\%$

Nuclear Decay

Reading Guide

FCAT Vocabulary

What You'll Learn

- Compare and contrast alpha, beta, and gamma radiation.
- Define the half-life of a radioactive material.
- Describe the process of radioactive dating.

Why It's Important

Nuclear decay produces nuclear radiation that can both harm people and be useful.

Review Vocabulary

electromagnetic wave: a transverse wave consisting of vibrating electric and magnetic fields

New Vocabulary

- alpha particle
- transmutation
- beta particle
- gamma ray
- half-life

Nuclear Radiation

When an unstable nucleus decays, particles and energy called nuclear radiation are emitted from it. The three types of nuclear radiation are alpha, beta (BAY tuh), and gamma radiation. Alpha and beta radiation are particles. Gamma radiation is an electromagnetic wave.

Alpha Particles

When alpha radiation occurs, an **alpha particle**—made of two protons and two neutrons, as shown in **Table 1**—is emitted from the decaying nucleus. An alpha particle is the same as the nucleus of a helium atom. It has a charge of +2 and an atomic mass of 4. Its symbol is the same as the symbol of a helium nucleus, ${}^4_2\text{He}$.

Reading Check What does an alpha particle consist of?

Activity

Nuclear Time Line With students, make a class time line of the important events in nuclear decay and radiation, beginning with Henri Becquerel's discovery of radioactivity. The time line could include contributions by Pierre and Marie Curie, Ernest Rutherford, Irène and Frédéric Joliot-Curie, Kasimir Fajans, Leo Szilard, Otto Hahn, Fritz Strassman, and Lise Meitner. [L3] Visual-Spatial

Teacher FYI

Smoke Detectors The detector shown in **Figure 7** is called an ionization detector. Another form of detector, the optical smoke detector, relies on detecting light scattering off particles in smoke.

Caption Answer

Figure 8 yes

Figure 7 When alpha particles collide with molecules in the air, positively charged ions and electrons result. The ions and electrons move toward charged plates, creating a current in the smoke detector.

Damage from Alpha Particles Alpha particles can be dangerous if they are released by radioactive atoms inside the human body. Biological molecules inside your body are large and easily damaged. A single alpha particle can damage many fragile biological molecules. Damage from alpha particles can cause cells not to function properly, leading to illness and disease.

Smoke Detectors Some smoke detectors give off alpha particles that ionize the surrounding air. Normally, an electric current flows through this ionized air to form a circuit, as in **Figure 7**. But if smoke particles enter the ionized air, they will absorb the ions and electrons. The circuit is broken and the alarm goes off.

Transmutation When an atom emits an alpha particle, it has two fewer protons, so it is a different element. **Transmutation** is the process of changing one element to another through nuclear decay. In alpha decay, two protons and two neutrons are lost from the nucleus. The new element has an atomic number two less than that of the original element. The mass number of the new element is four less than the original element. **Figure 8** shows a nuclear transmutation caused by alpha decay. The charge of the original nucleus equals the sum of the charges of the nucleus and the alpha particle that are formed.

Figure 8 In this transmutation, polonium emits an alpha particle and changes into lead.

Determine whether the charges and mass numbers of the products equal the charge and mass number of the polonium nucleus.

Reading Strategy

Question Have students preview the text and turn headings into questions. "Damage from Alpha Particles" could be turned into "How can alpha particles cause damage?" As students read, have them answer questions. Later have them revisit questions and answer from memory.

Figure 9 Nuclei that emit beta particles undergo transmutation. In beta decay shown here, iodine changes to xenon. **Compare** the total atomic number and mass number of the products with the atomic number and mass number of the iodine nucleus.

Beta Particles

A second type of radioactive decay is called beta decay, which is summarized in **Table 2**. Sometimes in an unstable nucleus a neutron decays into a proton and emits an electron. The electron is emitted from the nucleus and is called a **beta particle**. Beta decay is caused by another basic force called the weak force.

Because the atom now has one more proton, it becomes the element with an atomic number one greater than that of the original element. Atoms that lose beta particles undergo transmutation. However, because the total number of protons and neutrons does not change during beta decay, the mass number of the new element is the same as that of the original element. **Figure 9** shows a transmutation caused by beta decay.

Damage from Beta Particles Beta particles are much faster and more penetrating than alpha particles. They can pass through paper but are stopped by a sheet of aluminum foil. Just like alpha particles, beta particles can damage cells when they are emitted by radioactive nuclei inside the human body.

Gamma Rays

The most penetrating form of nuclear radiation is gamma radiation. **Gamma rays** are electromagnetic waves with the highest frequencies and the shortest wavelengths in the electromagnetic spectrum. They have no mass and no charge and travel at the speed of light. They usually are emitted from a nucleus when alpha decay or beta decay occurs. The properties of gamma rays are summarized in **Table 3**.

Thick blocks of dense materials, such as lead and concrete, are required to stop gamma rays. However, gamma rays cause less damage to biological molecules as they pass through living tissue. Suppose an alpha particle and a gamma ray travel the same distance through matter. The gamma ray produces fewer ions because it has no electric charge.

Table 2 Beta Particles

Symbol	$^0_{-1}\text{e}$

Inquiry Lab

Electromagnetic Radiation

Purpose to demonstrate the penetration of electromagnetic radiation, using light

Possible Materials flashlight, blue plastic wrap, red plastic wrap, clear plastic wrap, white T-shirt, aluminum foil, other materials students choose

Estimated Time 10–15 min

Teaching Strategies Have students shine a flashlight through various materials to observe if the light penetrates the material and hits the wall. Students can change the wavelength of the light by placing blue or red plastic wrap over the flashlight. If the light penetrates, measure how far back they can move and still see the light on the wall, then make a table summarizing their results. Repeat with any other materials they choose. Have them draw conclusions about the penetration of different wavelengths of light.

Discussion

Emitting Particles Have students summarize the effect on an atom's atomic mass (A) and atomic number (Z) if the atom emits an alpha particle, a beta particle, or a gamma ray. When an alpha particle is released, A decreases by four and Z decreases by two. When a beta particle is released, A is unchanged and Z increases by one. When gamma rays are released, A and Z are unchanged.

L2 **IS** Logical-Mathematical

Differentiated Instruction

English-Language Learners Have ELL students draw three lithium atoms with three electrons around the nucleus with a pencil. Have them erase one electron from each lithium atom, and explain that an ion is a atom missing an electron, and that ions have the capacity to transfer electrons, which is electricity.

Science Journal

Radiation Have students find out who chose alpha, beta, and gamma to name different kinds of radiation, why, and when, and write this information in their journals. Ernest Rutherford gave these names to these types of radiation for, as he said, simplicity. He named alpha and beta radiation between 1895 and 1898 and gamma rays in 1903. **L2** **IS** Linguistic

Radiation Detection

Materials Geiger counter, different samples of rock and bone

Estimated Time five minutes

Procedure Use the Geiger counter to detect radiation in samples of rock and bone, and to confirm that all materials have some radioactive material.

Virtual Labs

Half-Life How can you simulate the radioactive half-life of an element?

Figure 10 The half-life of ^3H is 12.3 years. During each half-life, half of the atoms in the sample decay into helium. **Infer** how many hydrogen atoms will be left in the sample after the next half-life.

Radioactive Half-Life

If an element is radioactive, how can you tell when its atoms are going to decay? Some radioisotopes decay to stable atoms in less than a second. However, the nuclei of certain radioactive isotopes require millions of years to decay. A measure of the time required by the nuclei of an isotope to decay is called the half-life. The **half-life** of a radioactive isotope is the amount of time it takes for half the nuclei in a sample of the isotope to decay. The nucleus left after the isotope decays is called the daughter nucleus. **Figure 10** shows how the number of decaying nuclei decreases after each half-life.

Half-lives vary widely among the radioactive isotopes. For example, polonium-214 has a half-life of less than a thousandth of a second, but uranium-238 has a half-life of 4.5 billion years. The half-lives of some other radioactive elements are listed in **Table 4**.

Reading Check What is a daughter nucleus?

Radioactive Dating

Some geologists, biologists, and archaeologists, among others, are interested in the ages of rocks and fossils found on Earth. The ages of these materials can be determined using radioactive isotopes and their half-lives. First, the amounts of the radioactive isotope and its daughter nucleus in a sample of material are measured. Then, the number of half-lives that need to pass to give the measured amounts of the isotope and its daughter nucleus is calculated. The number of half-lives is the amount of time that has passed since the isotope began to decay. Also, it is usually the amount of time that has passed since the object was formed, or the age of the object. Different isotopes are useful in dating different types of materials.

Table 4 Sample Half-Lives	
Isotope	Half-Life
^3_1H	12.3 years
$^{212}_{82}\text{Pb}$	10.6 hr
$^{14}_6\text{C}$	5,730 years
$^{211}_{84}\text{Po}$	0.5 s
$^{235}_{92}\text{U}$	7.04×10^8 years
$^{131}_{53}\text{I}$	8.04 days

Curriculum Connection

History Have students do research to learn how radioactive dating has been used to determine the ages of artifacts found in archaeological digs. Students might research Pompeii, China's terra-cotta army, or Easter Island. [L3] KS Linguistic

Differentiated Instruction

Challenge Have students investigate the process scientists use to determine the levels of radioactive isotopes and daughter nuclei present in a sample when performing carbon or uranium dating. Put the process in a flow chart. [L3]

Carbon Dating The radioactive isotope carbon-14 often is used to estimate the ages of plant and animal remains. Carbon-14 has a half-life of 5,730 years and is found in molecules such as carbon dioxide. Plants use carbon dioxide when they make food, so all plants contain carbon-14. When animals eat plants, carbon-14 is added to their bodies.

The decaying carbon-14 in a plant or animal is replaced when an animal eats or when a plant makes food. As a result, the ratio of the number of carbon-14 atoms to the number of carbon-12 atoms in the organism remains nearly constant. But when an organism dies, its carbon-14 atoms decay without being replaced. The ratio of carbon-14 to carbon 12 then decreases with time. By measuring this ratio, the age of an organism's remains can be estimated. However, only material from plants and animals that lived within the past 50,000 years contains enough carbon-14 to be measured.

Uranium Dating Radioactive dating also can be used to estimate the ages of rocks. Some rocks contain uranium, which has two radioactive isotopes with long half-lives. Each of these uranium isotopes decays into a different isotope of lead. The number of these uranium isotopes and their daughter nuclei are measured. From the ratios of these amounts, the number of half-lives since the rock was formed can be calculated.

section 2 review

Summary

Nuclear Radiation

- When an unstable nucleus decays it emits nuclear radiation that can be alpha particles, beta particles, or gamma rays.
- An alpha particle consists of two protons and two neutrons.
- A beta particle is an electron and is emitted when a neutron decays into a proton.
- Gamma rays are electromagnetic waves of very high frequency that usually are emitted when alpha decay or beta decay occurs.

Half-Life and Radioactive Dating

- The half-life of a radioactive isotope is the amount of time for half the nuclei in a sample of the isotope to decay.
- The amounts of radioactive isotopes and their daughter nuclei are needed to date materials.

Self Check

1. **Infer** how the mass number and the atomic number of a nucleus change when it emits a beta particle.
2. **Determine** the daughter nucleus formed when a radon-222 nucleus emits an alpha particle.
3. **Describe** how each of the three types of radiation can be stopped.
4. **Think Critically** Sample 1 contains nuclei with a half-life of 10.6 hr and sample 2 contains an equal number of nuclei with a half-life of 0.5 s. After 3 half-lives pass for each sample, which sample contains more of the original nuclei?

Applying Math

5. **Use Percentages** What is the percentage of radioactive nuclei left after 3 half-lives pass?
6. **Use Fractions** If the half-life of iodine-131 is 8 days, how much of a 5-g sample is left after 32 days?

More Section Review fl.gpscience.com

SECTION 2 Nuclear Decay 795

section 2 review

1. The atomic number increases by one and the mass number doesn't change.
2. $^{222}_{86}\text{Rn} \rightarrow ^{218}_{84}\text{Po} + ^4_2\text{He}$; polonium
3. alpha particles: sheet of paper; beta particles: sheet of metal foil; gamma rays: thick blocks of lead or concrete
4. They contain the same number. After three half lives, each sample contains one eighth of the original number of nuclei, which was the same for both samples.
5. 12.5%
6. 32 days = 4 half-lives = 1/16 of original number of nuclei left; $1/16 \times 5 \text{ g} = 0.3 \text{ g}$ left

Detecting Radiation Our five senses allow us to see, hear, smell, taste, and feel, but none of our senses can tell us when we are being exposed to radioactivity. In this section, students will learn about four methods for detecting radiation.

Vocabulary Usage Have students find the figures that illustrate each new vocabulary term. *Cloud chamber*, *bubble chamber*, and *Geiger counter* all are shown in the text. Ask them to say the vocabulary word as they focus on the associated picture. Pairing pictures with words helps support vocabulary development.

Reading Guide

What You'll Learn

- **Describe** how radioactivity can be detected in cloud and bubble chambers.
- **Explain** how an electroscope can be used to detect radiation.
- **Explain** how a Geiger counter can measure nuclear radiation.

Why It's Important

Devices that detect and measure radioactivity are used to monitor exposure to humans.

Review Vocabulary

ion: an atom that has gained or lost electrons

New Vocabulary

- cloud chamber
- bubble chamber
- Geiger counter

Radiation Detectors

Because you can't see or feel alpha particles, beta particles, or gamma rays, you must use instruments to detect their presence. Some tools that are used to detect radioactivity rely on the fact that radiation forms ions in the matter it passes through. The tools detect these newly formed ions in several ways.

Cloud Chambers A **cloud chamber**, shown in **Figure 11**, can be used to detect alpha or beta particle radiation. A cloud chamber is filled with water or ethanol vapor. When a radioactive sample is placed in the cloud chamber, it gives off charged alpha or beta particles that travel through the water or ethanol vapor. As each charged particle travels through the chamber, it knocks electrons off the atoms in the air, creating ions. It leaves a trail of ions in the chamber. The water or ethanol vapor condenses around these ions, creating a visible path of droplets along the track of the particle. Beta particles leave long, thin trails, and alpha particles leave shorter, thicker trails.

Reading Check Why are trails produced by alpha and beta particles seen in cloud chambers?

Figure 11 If a sample of radioactive material is placed in a cloud chamber, a trail of condensed vapor will form along the paths of the emitted particles.

Reinforcement, p. 29

Mathematics Skill Activities, p. 31

 Reading Check

Answer The charged particles knock electrons off atoms in the air, leaving a trail of ions. The vapor condenses around these ions.

Use an Analogy

Vapor Trails Tell students that the vapor trails sometimes seen behind jet airplanes are made up of water droplets that have condensed around the jet's exhaust fumes. Like the trails in cloud chambers, vapor trails provide a visual record of the path of the object that caused them.

Visual Learning

Figure 12 Point out to students that at the lower part of this bubble chamber photograph, particles collide and create a spray of charged particles. A magnetic field perpendicular to the page deflects the particles so that those curling to the left must have an opposite charge to those curling to the right. Note that only charged particles are visible.

Figure 12 Particles of nuclear radiation can be detected as they leave trails of bubbles in a bubble chamber.

Figure 13 Nuclear radiation can cause an electroscope to lose its charge.

Bubble Chambers Another way to detect and monitor the paths of nuclear particles is by using a bubble chamber. A **bubble chamber** holds a superheated liquid, which doesn't boil because the pressure in the chamber is high. When a moving particle leaves ions behind, the liquid boils along the trail. The path shows up as tracks of bubbles, like the ones in **Figure 12**.

Electroscopes Do you remember how an electroscope can be used to detect electric charges? When an electroscope is given a negative charge, its leaves repel each other and spread apart, as in **Figure 13A**. They will remain apart until their extra electrons have somewhere to go and discharge the electroscope. The excess charge can be neutralized if it combines with positive charges. Nuclear radiation moving through the air can remove electrons from some molecules in air, as shown in **Figure 13B**, and cause other molecules in air to gain electrons. When this occurs near the leaves of the electroscope, some positively charged molecules in the air can come in contact with the electroscope and attract the electrons from the leaves, as **Figure 13C** shows. As these negatively charged leaves lose their charges, they move together. **Figure 13D** shows this last step in the process. The same process also will occur if the electroscope leaves are positively charged. Then the electrons move from negative ions in the air to the electroscope leaves.

A The electroscope leaves are charged with negative charge.

B Nuclear radiation, such as alpha particles, can create positive ions.

C Negative charges move from the leaves to positively charged ions.

D The electroscope leaves lose their negative charge and come together.

SECTION 3 Detecting Radioactivity 797

Teacher FYI

Bubble Chamber The bubble chamber, developed in the 1950s, was used by scientists for many years to observe the particles in matter. It has since been replaced by newer, more complex detectors.

 IDENTIFYING
Misconceptions

Fundamental Particles Students might assume that electrons, protons, and neutrons are the smallest possible particles. Explain that electrons are fundamental particles, but that protons and neutrons are composite particles made up of smaller particles called quarks.

Quick Demo

Tracking Radiation Exposure

Materials Radiation film badge

Time Required 2–5 minutes

Procedure People whose work involves possible exposure to radiation are required to wear film badges that record the amount of radiation the person has received. You can obtain one of these badges from the radiation laboratory at a hospital. Explain to students that a small piece of film is encased in a plastic holder. The casing is light-tight so the film responds only to alpha, beta, and gamma radiation, not visible light. Every month, the film is removed and the amount of radiation it (and therefore the wearer) has received is measured. New film is then inserted in the holder.

Radiation Units There are several units for measuring radiation. The curie and the becquerel are based on the number of disintegrations per second. The roentgen, the rad, and the gray measure the effect radiation has on the absorbing material. The rem is used to measure biological damage to humans.

Measuring Radiation

It is important to monitor the amount of radiation a person is being exposed to because large doses of radiation can be harmful to living tissue. A **Geiger counter** is a device that measures the amount of radiation by producing an electric current when it detects a charged particle.

Applying Math Use Logarithms

THE AGE OF ROCKS The radioactive nucleus uranium-238 produces the daughter nucleus lead-206 with a half-life of 4.5 billion years. The age of a mineral sample can be calculated from the equation:

$$\text{age} = (1.44H) \ln \left[1 + \frac{N_L}{N_U} \right]$$

In this equation, H is the half-life of uranium 238, N_L is the number of lead-206 atoms in the sample, and N_U is the number of uranium-238 atoms in the sample. Find the age of a sample in which the ratio N_L/N_U is measured to be 0.55.

IDENTIFY known values and unknown values

Identify the known values:

the ratio of the number of uranium-238 atoms $\rightarrow \frac{N_L}{N_U} = 0.55$
to the number of lead-206 atoms is 0.55

a half-life of 4.5 billion years $\rightarrow H = 4.5$ billion years

Identify the unknown value:

what is the age of the sample? $\rightarrow \text{age} = ?$ years

SOLVE the problem

Substitute the known values into the equation for the age:

$$\begin{aligned} \text{age} &= (1.44H) \ln \left[1 + \frac{N_L}{N_U} \right] = (1.44 \times 4.5 \text{ billion yrs}) \ln [1 + 0.55] \\ &= (6.48 \text{ billion yrs}) \ln(1.55) \end{aligned}$$

To calculate $\ln(1.55)$, enter 1.55 on your calculator and press the “ln” button. The result is 0.438. Substitute this value in the above equation:

$$\text{age} = (6.48 \text{ billion yrs})(0.438) = 2.84 \text{ billion yrs}$$

CHECK the answer

Does your answer seem reasonable? The ratio $N_L/N_U = 0.55$, means that less than one half-life has elapsed. The calculated age is less than one half-life.

Practice Problems

Find the age of a sample in which the ratio N_L/N_U has been measured to be 1.21.

For more practice problems go to page 879, and visit Math Practice at fl.gpscience.com.

Active Reading

Metacognition Journal In this strategy, each student analyzes his or her own thought processes. Have students divide a sheet of paper in half. On the left, have them record what they have learned about radiation detection. On the right, have them record the reason they learned it.

Figure 14 Electrons that are stripped off gas molecules in a Geiger counter move to a positively charged wire in the device. This causes current to flow in the wire. The current then is used to produce a click or a flash of light.

Geiger Counters A Geiger counter, shown in **Figure 14**, has a tube with a positively charged wire running through the center of a negatively charged copper cylinder. This tube is filled with gas at a low pressure. When radiation enters the tube at one end, it knocks electrons from the atoms of the gas. These electrons then knock more electrons off other atoms in the gas, and an “electron avalanche” is produced. The free electrons are attracted to the positive wire in the tube. When a large number of electrons reaches the wire, a short, intense current is produced in the wire. This current is amplified to produce a clicking sound or flashing light. The intensity of radiation present is determined by the number of clicks or flashes of light each second.

✓ Reading Check How does a Geiger counter indicate that radiation is present?

Background Radiation

It might surprise you to know that you are bathed in radiation that comes from your environment. This radiation, called background radiation, is not produced by humans. Instead it is low-level radiation emitted mainly by naturally occurring radioactive isotopes found in Earth’s rocks, soils, and atmosphere. Building materials such as bricks, wood, and stones contain traces of these radioactive materials. Traces of naturally occurring radioactive isotopes are found in the food, water, and air consumed by all animals and plants. As a result, animals and plants also contain small amounts of these isotopes.

Artificial Rainmaking It may be possible to ease the health and economic hardships caused by severe droughts by artificially making rain. The formation of raindrops in a cloud is similar to the formation of droplets in a cloud chamber. Rain forms when cold droplets freeze around microscopic particles of dust, and then melt as they fall through warmer air. Research artificial rainmaking and report your findings to your class.

Artificial Rainmaking Scientists have tried three ways to make artificial rain. Have students research artificial rain to learn how the methods work. One method is spraying water into warm clouds. Another method is to drop dry ice into clouds. The third method is to drop silver iodide crystals or similar crystals into clouds. None of these methods have been very successful.

Discussion

Radiation Badges What occupations might require a radiation badge to monitor exposure to radiation? Possible answers: nuclear power plant workers; sailors on nuclear-powered ships and submarines; doctors, nurses, dentists, airport security workers (X-ray exposure); scientists doing research with radioactive materials

✓ Reading Check

Answer by a clicking sound or flashing light

Activity

Background Radiation Have students do research to find out about sources of background radiation in their community.

L2 **IS** **Linguistic**

Post Reading

Fix-Up Strategy Ask students to re-read a part of the text they found difficult. When they encounter problems with comprehension, tell students to read ahead for clarification. Remind students to slow down when confronting difficult text and speed up when they want a sense of the overall idea.

Differentiated Instruction

Visually Impaired If you have a Geiger counter, let your visually impaired students hear the difference in the clicking between different materials. If you don’t have a Geiger counter, do a web search for Geiger counter sounds and download a sound file for them to hear.

Teacher FYI

The G-M Counter The Geiger counter was invented by a German physicist named Hans Geiger. In 1928, Geiger, along with Walther Müller, improved the detector, so it is often called the Geiger-Müller counter, or simply the G-M counter.

Visual Learning

Figure 15 According to this circle graph, how much of the background radiation received by an average person in the United States comes from sources outside the body? **at least 89 percent**

3 Assess

Check For Understanding

Visual-Spatial Ask students to draw sketches of pictures that might be obtained with a cloud chamber and a bubble chamber. For each sketch, have the students explain the lines they have drawn and which type of particle would cause that type of line. **L2** **IS** **P**

Reteach

Natural Radioactivity Have students explain why radiation occurs naturally in the human body. **Radioactive isotopes of elements used by the body occur in nature and are used in the same way as the stable isotopes of the same elements.** **L2** **IS** **Logical-Mathematical**

Sources of Background Radiation

Figure 15 This circle graph shows the average amount of background radiation from different sources received by a person living in the United States.

Sources of Background Radiation Background radiation comes from several sources, as shown in **Figure 15**. The largest source comes from the decay of radon gas. Radon, which emits an alpha particle when it decays, is produced in Earth's crust by the decay of uranium-238. Radon gas can seep into houses and basements from the surrounding soil and rocks.

Some background radiation comes from high-speed nuclei, called cosmic rays, that strike Earth's atmosphere. They produce showers of particles, including alpha, beta, and gamma radiation. Most of this radiation is absorbed by the atmosphere. Higher up there is less atmosphere to absorb this radiation, so the background radiation from cosmic rays increases with altitude.

Radiation in Your Body Some of the elements that are essential for life have naturally occurring radioactive isotopes. For example, about one out of every trillion carbon atoms is carbon-14, which emits a beta particle when it decays. With each breath, you inhale about 3 million carbon-14 atoms.

The amount of background radiation a person receives can vary greatly. The amount depends on the type of rocks underground, the type of materials used to construct the person's home, and the elevation at which the person lives, among other things. However, because it comes from naturally occurring processes, background radiation never can be eliminated.

section 3 review

Summary

Radiation Detectors

- Alpha and beta particles can be detected by the trail of ions they form when they pass through a cloud chamber or a bubble chamber.
- The presence of alpha or beta particles can cause an electroscope to become discharged.
- A Geiger counter is used to measure radiation levels. It produces a clicking sound or a flash of light when alpha or beta particles enter the Geiger counter tube.

Background Radiation

- Background radiation is low-level radiations emitted mainly by radioactive isotopes in Earth's rocks, soils, and atmosphere.
- The largest source of background radiation is from the alpha decay of radon gas.

Self Check

1. **Describe** why a charged electroscope will discharge when placed near a radioactive material.
2. **Compare and contrast** cloud and bubble chambers.
3. **Describe** the process that occurs in a Geiger counter when radiation is detected.
4. **Explain** why background radiation never can be completely eliminated.
5. **Think Critically** If the radioactive isotope radon-222 has a half-life of only four days, how can radon gas be continually present inside houses?

Applying Math

6. **Use Percentages** The amount of radiation can be measured in units called millirems. If 25 millirems from cosmic rays is 8.0 percent of the average background radiation, what is the amount of the average background radiation in millirems?

section 3 review

1. Nuclear radiation causes some molecules in air to become positively charged. Negative charges on the electroscope leaves move from the leaves to the positively charged ions.
2. Both show the paths of ions created by radiation. In bubble chambers a liquid boils along the trail of the ions. In cloud chambers, vapor condenses around the ions.
3. A charged particle strikes a gas molecule in the tube, knocking off electrons. These electrons are attracted to a positively charged wire in the tube, producing more electrons as they collide with gas molecules. The current is amplified to produce a click.
4. Natural sources of background radiation include the decay of radioactive materials in rocks and soil, and cosmic rays, which cannot be eliminated.
5. Radon gas is continually produced by the decay of the isotope uranium-238, which has a half-life of 4.5 billion years.
6. Set up a ratio: $(25 \text{ millirem})/x = 0.08$; so $x = (25 \text{ millirem})/0.08 = 312 \text{ millirem}$

Nuclear Reactions

Reading Guide

What You'll Learn

- **Explain** nuclear fission and how it can begin a chain reaction.
- **Discuss** how nuclear fusion occurs in the Sun.
- **Describe** how radioactive tracers can be used to diagnose medical problems.
- **Discuss** how nuclear reactions can help treat cancer.

Why It's Important

Almost all of the different atoms that you are made of were formed by the nuclear reactions inside ancient, distant stars.

Review Vocabulary

kinetic energy: energy of motion; increases as the mass or speed of an object increases

New Vocabulary

- **nuclear fission**
- chain reaction
- critical mass
- **nuclear fusion**
- tracer

Nuclear Fission

In the 1930s, physicist Enrico Fermi thought that by bombarding nuclei with neutrons, nuclei would absorb neutrons and heavier nuclei would be produced. However, in 1938, Otto Hahn and Fritz Strassmann found that when a neutron strikes a uranium-235 nucleus, the nucleus splits apart into smaller nuclei.

In 1939 Lise Meitner was the first to offer a theory to explain these results. She proposed that the uranium-235 nucleus is so distorted when the neutron strikes it that it divides into two smaller nuclei, as shown in **Figure 16**. The process of splitting a nucleus into several smaller nuclei is **nuclear fission**. The word *fission* means “to divide.”

Reading Check

What initiates nuclear fission of a uranium-235 nucleus?

Only large nuclei, such as the nuclei of uranium and plutonium, undergo nuclear fission. A fission reaction usually produces several individual neutrons in addition to the smaller nuclei. The total mass of the products is slightly less than the mass of the original nucleus and the neutron. This small amount of missing mass is converted to a tremendous amount of energy during the fission reaction.

Figure 16 When a neutron hits a uranium-235 nucleus, the uranium nucleus splits into two smaller nuclei and two or three free neutrons. Energy also is released.

Tie to Prior Knowledge

Breaking and Combining Fission means breaking things apart and fusion means putting things together. Ask students to give examples of processes they know that fit these definitions. In this section they will learn about nuclear fission and nuclear fusion.

Connections Connect new vocabulary words to more familiar terms. For instance, *nuclear fission* might be linked to *splitting nucleus*. Write the vocabulary term and the associated word on a chart. Ask students to visualize the associated word when they hear or see the vocabulary term.

2 Teach

✓ Reading Check

Answer A neutron striking the nucleus causes it to split.

Quick Demo

Atomic Forces

Materials kinetic toy—several ball bearings suspended by two strings in contact with each other.

Time Required 1–3 min

Procedure Explain the forces at work in splitting an atom. The kinetic energy of a neutron is high enough to disrupt the strong force in the target nucleus, causing the atom to split into more stable configurations. At this point demonstrate the kinetic energy of the neutron by lifting one of the outside balls and dropping it to see the kinetic energy transmitted through the intermediary balls to the opposite outside ball and observe that ball flying out from the group.

Purpose Students model a nuclear reaction. **L2 ELL KS** Kinesthetic

Materials marbles, beaker, modeling clay

Teaching Strategy Emphasize that the marbles taken out represent nuclei that decay but do not disappear; they change into nuclei of a different element.

Analysis

1. one minute
2. No. The waste products might be radioactive. They will not undergo fission.

Assessment

Oral What was the half-life of the marbles with clay? How many were left after 5 min? **1 min;** **one** Use PASC, p. 101.

Figure 17 A chain reaction occurs when neutrons emitted from a split nucleus cause other nuclei to split and emit additional neutrons.

Modeling a Nuclear Reaction

Procedure

1. Place 32 marbles, each with an attached lump of clay, into a large beaker. These marbles with clay represent unstable atoms.
2. During a 1-min period, remove half of the marbles and pull off the clay. Place the removed marbles into another beaker and place the lumps of clay into a pile. Marbles without clay represent stable atoms. The clay represents waste from the reaction—smaller atoms that still might decay and give off energy.
3. Repeat this procedure four more times.

Analysis

1. What is the half-life of this reaction?
2. Explain whether the waste products could undergo nuclear fission.

Mass and Energy Albert Einstein proposed that mass and energy were related in his special theory of relativity. According to this theory, mass can be converted to energy and energy can be converted to mass. The relation between mass and energy is given by this equation:

Mass-Energy Equation

$$\text{Energy (joules)} = \text{mass (kg)} \times [\text{speed of light (m/s)}]^2$$

$$E = mc^2$$

A small amount of mass can be converted into an enormous amount of energy. For example, if one gram of mass is converted to energy, about 100 trillion joules of energy are released.

Chain Reactions When a nuclear fission reaction occurs, the neutrons emitted can strike other nuclei in the sample and cause them to split. These reactions then release more neutrons, causing additional nuclei to split, as shown in **Figure 17**. The series of repeated fission reactions caused by the release of neutrons in each reaction is a **chain reaction**.

If the chain reaction is uncontrolled, an enormous amount of energy is released in an instant. However, a chain reaction can be controlled by adding materials that absorb neutrons. If enough neutrons are absorbed, the reaction will continue at a constant rate.

For a chain reaction to occur, a critical mass of material that can undergo fission must be present. The **critical mass** is the amount of material required so that each fission reaction produces approximately one more fission reaction. If less than the critical mass of material is present, a chain reaction will not occur.

Science Journal

Nuclear Energy? Advocates claim that nuclear reactors are a safe, clean method of producing electricity. Opponents argue that because of the danger from spent nuclear fuel and nuclear waste, reactors should be permanently shut down. Have students write their opinions on this issue in their Science Journals. **L2 KS** Linguistic

Differentiated Instruction

Physically Disabled Pair students who cannot manipulate the marbles with students who can. Have the student with disabilities in each pair calculate the number of marbles to be processed during each one-minute period, and keep track of the number of marbles processed.

Nuclear Fusion

Even though nuclear fission reactions release tremendous amounts of energy, even more energy can be released by nuclear fusion reactions. In a **nuclear fusion** reaction, two nuclei with small masses combine to form a nucleus of larger mass. Nuclear fusion reactions release millions of times more energy than can be released by chemical reactions.

The reason nuclear reactions release so much more energy than chemical reactions is that the strong force is much stronger than the electric force. This means that the nuclear potential energy stored in atomic nuclei is much greater than the chemical potential energy stored in chemical bonds between atoms.

Temperature and Fusion For nuclear fusion to occur, positively charged nuclei must get close to each other. However, nuclei repel each other because they have the same positive electric charge. If nuclei are moving fast, they can have enough kinetic energy to overcome the repulsive electrical force between them and get close to each other.

Remember that the kinetic energy of atoms or molecules increases as their temperature increases. Only at temperatures of millions of degrees Celsius are nuclei moving so fast that they can get close enough for fusion to occur. These extremely high temperatures are found in the center of stars, such as the Sun.

Nuclear Fusion and the Sun The Sun is composed mainly of hydrogen. Most of the energy given off by the Sun is produced by a process involving the fusion of hydrogen nuclei. This process occurs in several stages, and one of the stages is shown in **Figure 18**. The net result of this process is that four hydrogen nuclei are converted into one helium nucleus. As these nuclear reactions occur, a small amount of mass is changed into an enormous amount of energy. Earth receives a small amount of this energy as thermal energy and light.

As the Sun ages, the hydrogen nuclei are used up as they are converted into helium. So far, only about one percent of the Sun's mass has been converted into energy. It is estimated that the Sun has enough hydrogen to keep this reaction going for another 5 billion years.

Scienceonline

Topic: Fusion Reactors

Visit fl.gpscience.com for Web links to information about the use of nuclear fusion as a future energy source.

Activity Write a paragraph describing the different types of fusion reactors that have been developed.

Figure 18 The fusion of hydrogen to form helium takes place in several stages in the Sun. One of these stages is shown here. An isotope of helium is produced when a proton and the hydrogen isotope H-2 undergo fusion.

Make a Model

Clay Nuclei Have students model fusion by using small balls of clay to show how two nuclei can join to become one larger nucleus. They should use different colors of clay to represent protons and neutrons. An easy reaction to model is the one in which a deuterium nucleus (hydrogen with one neutron) and a tritium nucleus (hydrogen with two neutrons) combine to form a helium nucleus and one neutron. Point out that when the number of protons changes, a nucleus of a new element is formed. [L2]

Kinesthetic

Teacher FYI

Hydrogen Bomb Scientists have been unable to achieve controlled fusion because the high temperature needed to initiate the reaction creates plasma that is difficult to contain. A hydrogen bomb, however, uses uncontrolled fusion. Inside the hydrogen bomb's casing, an atomic bomb uses fission to create the extreme temperatures needed to start the fusion reaction.

Use Science Words

Word Meaning Have students explain why the fusion of hydrogen nuclei on the Sun is called a thermonuclear reaction. *Thermo-* comes from a Greek word meaning "heat." Forcing hydrogen nuclei to fuse requires extreme heat. [L3] **Linguistic**

Reading Strategy

Infer This skill involves reading carefully to interpret meaning. Students might read: If less critical mass of material is present, a chain reaction will not occur. They could infer: If there's more critical mass, a chain reaction will occur. Have them practice making inferences.

Fun Fact

The submarines of the U.S. Navy are powered by nuclear reactors.

Radioactive Decay Equations The atomic number of barium is 56 and the atomic number of krypton is 36. These add up to 92. Uranium-235 breaks into neodymium (atomic number 60) and germanium (atomic number 32).

Research Potassium-40 decays to form two other isotopes. Research to learn what these isotopes are. **argon-40 and calcium-40**

Discussion

Tracers How is the use of tracers similar to the use of radio collars in tracking wild animals? The collars emit an electromagnetic signal that can be detected with an antenna and receiver. This allows scientists to determine the movement of the animal. Similarly, a radioactive tracer emits radiation, which allows physicians to track its movement in the body. **L2** **IS** **Logical-Mathematical**

Reading Check

Answer by detecting the radioactivity they emit

Caption Answer

Figure 19 Iodine is naturally taken up by the thyroid. Also, it allows doctors to determine how well the thyroid is functioning without having to actually look at it.

Content Background

A malfunctioning thyroid may produce too much or too little of the hormones necessary for your body to function properly. These conditions are called hyperthyroidism and hypothyroidism, respectively. Iodine is a main ingredient in the two most important hormones produced by the thyroid. A hyperthyroid patient given radioactive iodine will show an excessive level of thyroid radioactivity. The opposite occurs in hypothyroidism.

Radioactive Decay Equations A uranium-235 atom can fission, or break apart, to form barium and krypton. Use a periodic table to find the atomic numbers of barium and krypton. What do they add up to? A uranium-235 atom can fission in several other ways such as producing neodymium and another element. What is the other element?

Figure 19 Radioactive iodine-131 accumulates in the thyroid gland and emits gamma rays, which can be detected to form an image of a patient's thyroid.

List some advantages of being able to use iodine-131 to form an image of a thyroid.

804 CHAPTER 25 Nuclear Changes

Using Nuclear Reactions in Medicine

If you were going to meet a friend in a crowded area, it would be easier to find her if she told you that she would be wearing a red hat. In a similar way, scientists can find one molecule in a large group of molecules if they know that it is “wearing” something unique. Although a molecule can’t wear a red hat, if it has a radioactive atom in it, it can be found easily in a large group of molecules, or even in a living organism. Radioactive isotopes can be located by detecting the radiation they emit.

When a radioisotope is used to find or keep track of molecules in an organism, it is called a **tracer**. Scientists can use tracers to follow where a particular molecule goes in your body or to study how a particular organ functions. Tracers also are used in agriculture to monitor the uptake of nutrients and fertilizers. Examples of tracers include carbon-11, iodine-131, and sodium-24. These three radioisotopes are useful tracers because they are important in certain body processes. As a result, they accumulate inside the organism being studied.

Reading Check

How are tracers located inside the human body?

Iodine Tracers in the Thyroid The thyroid gland is located in your neck and produces chemical compounds called hormones. These hormones help regulate several body processes, including growth. Because the element iodine accumulates in the thyroid, the radioisotope iodine-131 can be used to diagnose thyroid problems. As iodine-131 atoms are absorbed by the thyroid, their nuclei decay, emitting beta particles and gamma rays. The beta particles are absorbed by

the surrounding tissues, but the gamma rays penetrate the skin. The emitted gamma rays can be detected and used to determine whether the thyroid is healthy, as shown in **Figure 19**. If the detected radiation is not intense, then the thyroid has not properly absorbed the iodine-131 and is not functioning properly. This could be due to the presence of a tumor. **Figure 20** shows how radioactive tracers are used to study the brain.

Differentiated Instruction

Challenge Have students investigate other ways that tracers are used in medicine and prepare a report on one method. If possible, they should interview a physician who uses tracers to find out drawbacks and benefits of the procedure. **Possible topics are tracers used to detect problems with the heart, kidneys, or digestion.** **L3** **IS** **Linguistic**

Visual Learning

Figure 19 Point out that the picture to the left shows the thyroid after the person has ingested the iodine-131 tracer. The red and orange colors indicate areas in which the iodine is well absorbed. Have students each find his or her thyroid gland, which is located in the neck between the larynx and the trachea. **L2** **IS** **Visual-Spatial**

Figure 20

The diagram below shows an imaging technique known as Positron Emission Tomography, or PET. Positrons are emitted from the nuclei of certain radioactive isotopes when a proton changes to a neutron. PET can form images that show the level of activity in different areas of the brain. These images can reveal tumors and regions of abnormal brain activity.

B The radioactive isotope fluorine-18 emits positrons when it decays. Fluorine-18 atoms are chemically attached to molecules that are absorbed by brain tissue. These compounds are injected into the patient and carried by blood to the brain.

C Inside the patient's brain, the decay of the radioactive fluorine-18 nuclei emits positrons that collide with electrons. The gamma rays that are released are sensed by the detectors.

D A computer uses the information collected by the detectors to generate an image of the activity level in the brain. This image shows normal activity in the right side of the brain (red, yellow, green) but below-normal activity in the left (purple).

A When positrons are emitted from the nucleus of an atom, they can hit electrons from other atoms and become transformed into gamma rays.

SECTION 4 Nuclear Reactions 805

Visualizing PET Scans

Have students examine the pictures and read the captions. Then ask the following questions:

What is a positron? A positron has the same mass as an electron but a positive charge. It can be considered a positively charged electron.

What is formed when a positron and electron combine? gamma rays

Why is it important for the fluorine-18 to be chemically attached to substances that are normally absorbed by the brain? The fluorine-18 needs to be absorbed in the brain tissue because that is the area that is being studied.

Activity

Positron Posters Have the students research how positrons are formed. Suggest students make posters illustrating their findings and present their posters to the class. L2 IS **Visual-Spatial** P

Post Reading

Debate Have students research nuclear reactions to determine the pros and cons of nuclear energy use. Engage the class in a debate with the following prompt: Do the benefits of using nuclear energy outweigh the risks?

3 Assess

DAILY INTERVENTION

Check for Understanding

Logical-Mathematical Ask students to explain why chain reactions do not occur in naturally existing material. **Fission occurs only for certain rare isotopes. The percentage of these isotopes in naturally existing material is so low that a chain reaction is unlikely.**

Reteach

Chain Reactions Have students discuss why a critical mass is necessary to keep a fission reaction going but not to keep a fusion reaction going. In a fission reaction, a particle bombards a nucleus and splits it into two nuclei plus several neutrons. If these neutrons hit other fissionable nuclei, those nuclei will split and produce new particles. This chain reaction will continue as long as there is enough fissionable material nearby. The amount needed to keep the reaction going is the critical mass. A fusion reaction is not a chain reaction.

Logical-Mathematical

Assessment

Content Many benefits result from nuclear applications in medicine, but there are disadvantages, too. Ask students to write newspaper articles explaining how radiation can cause as well as treat cancer. Possible answers: It can cause mutations in cell structures, leading to tumor formation, or it can kill cancer cells. Use PASC, p. 141.

Figure 21 Cancer cells, such as the ones shown here, can be killed with carefully measured doses of radiation.

Treating Cancer with Radioactivity

When a person has cancer, a group of cells in that person's body grows out of control and can form a tumor. Radiation can be used to stop some types of cancerous cells from growing. Remember that the radiation that is given off during nuclear decay is strong enough to ionize nearby atoms. If a source of radiation is placed near cancer cells, such as those shown in **Figure 21**, atoms in the cells can be ionized. If the ionized atoms are in a

critical molecule, such as the DNA or RNA of a cancer cell, then the molecule might no longer function properly. The cell then could die or stop growing.

When possible, a radioactive isotope such as gold-198 or iridium-192 is implanted within or near the tumor. Other times, tumors are treated from outside the body. Typically, an intense beam of gamma rays from the decay of cobalt-60 is focused on the tumor for a short period of time. The gamma rays pass through the body and into the tumor. How can physicians be sure that only the cancer cells will absorb radiation? Because cancer cells grow quickly, they are more susceptible to absorbing radiation and being damaged than healthy cells are. However, other cells in the body that grow quickly also are damaged, which is why cancer patients who have radiation therapy sometimes experience severe side effects.

section 4 review

Summary

Nuclear Fission

- Nuclear fission occurs when a neutron strikes a nucleus, causing it to split into smaller nuclei.
- A chain reaction requires a critical mass of fissionable material.

Nuclear Fusion

- Nuclear fusion occurs when two nuclei combine to form another nucleus.
- Nuclear fusion occurs at temperatures of millions of degrees, which occur inside the Sun.

Medical Uses of Radiation

- Radioactive isotopes are used as tracers to locate various atoms or molecules in organisms.
- Radiation emitted by radioactive isotopes is used to kill cancer cells.

Self Check

1. **Infer** whether mass is conserved in a nuclear reaction.
2. **Explain** why fusion reactions can occur inside stars.
3. **Explain** how a chain reaction can be controlled.
4. **Describe** two properties of a tracer isotope used for monitoring the functioning of an organ in the body.
5. **Think Critically** Explain why high temperatures are needed for fusion reactions to occur, but not for fission reactions to occur.

Applying Math

6. **Calculate Number of Nuclei** In a chain reaction, two neutrons are emitted by each nucleus that is split. If one nucleus is split in the first step of the reaction, how many nuclei will have been split after the fifth step?

section 4 review

1. No. Some of the mass in the initial nuclei is converted into energy.
2. Fusion reactions require extremely high temperatures to get started. These temperatures occur in the interior of stars.
3. By absorbing some of the neutrons emitted when fission occurs.
4. The isotope must be absorbed by the organ being studied, and must have a half life sufficiently long for the study to be completed before it decays away.
5. In order for the strong force to act and fusion to occur, nuclei must be moving fast enough to overcome the electrical repulsion between them. The necessary speeds occur only at high temperatures. Fission does not require high speeds because neutrons are not electrically repulsed by the nucleus.
6. step 1 : 1; step 2 : 2; step 3 : 4; step 4 : 8; step 5 : 16

Chain Reactions

In an uncontrolled nuclear chain reaction, the number of reactions increases as additional neutrons split more nuclei. In a controlled nuclear reaction, neutrons are absorbed, so the reaction continues at a constant rate. How could you model a controlled and an uncontrolled nuclear reaction in the classroom?

Real-World Problem

How can you use dominoes to model chain reactions?

Goals

- **Model** a controlled and uncontrolled chain reaction.
- **Compare** the two types of chain reactions.

Materials

dominoes stopwatch

Procedure

1. Set up a single line of dominoes standing on end so that when the first domino is pushed over, it will knock over the second and each domino will knock over the one following it.
2. Using the stopwatch, time how long it takes from the moment the first domino is pushed over until the last domino falls over. Record the time.
3. Using the same number of dominoes as in step 1, set up a series of dominoes in which at least one of the dominoes will knock down two others, so that two lines of dominoes will continue falling. In other words, the series should have at least one point that looks like the letter Y.
4. Repeat step 2.

Conclude and Apply

1. **Compare** the amount of time it took for all of the dominoes to fall in each of your two arrangements.
2. **Determine** the average number of dominoes that fell per second in both domino arrangements.
3. **Identify** which of your domino arrangements represented a controlled chain reaction and which represented an uncontrolled chain reaction.
4. **Describe** how the concept of critical mass was represented in your model of a controlled chain reaction.
5. Assuming that they had equal amounts of material, which would finish faster—a controlled or an uncontrolled nuclear chain reaction? Explain.

Communicating Your Data

Explain to friends or members of your family how a controlled nuclear chain reaction can be used in nuclear power plants to generate electricity.

LAB 807

Communicating Your Data

Students should prepare an illustration of a controlled and an uncontrolled reaction to help explain what is taking place.

Video Lab available.

Real-World Problem

Purpose Students model controlled and uncontrolled chain reactions. **L2** **IN** **Kinesthetic**

Process Skills collect data, make models, compare and contrast, draw conclusions

Time Required 40 min

Procedure

Teaching Strategy Students can collect additional data by forming large groups and using all of their dominoes to form longer chains.

Conclude and Apply

1. The Y-shaped arrangement fell faster.
2. Answers will vary.
3. The straight arrangement represented a controlled reaction because any neutron that split off was absorbed. The Y-shaped arrangement represented an uncontrolled reaction.
4. Critical mass was represented because the reaction stopped when the fissionable material (dominoes) was used up.
5. An uncontrolled reaction would finish faster because a single reaction could produce two reactions which could produce four reactions and so on.

Assessment

Content Have students write and perform a skit that demonstrates controlled and uncontrolled reactions. Use **Performance Assessment in the Science Classroom**, p. 147.

Real-World Problem

Purpose Students will model the decay of a uranium atom through the process of transmutation. **L2** **KS** **Kinesthetic**

Process Skills make a model, compare and contrast, identify, infer

Time Required one 45-minute class period

Possible Materials Students can use any small objects in place of the rice, beans, or candy. A strong bonding glue should be used when constructing the model.

Safety Precautions Never eat foods used in the lab.

Discussion

Radioactive Substances Ask students to think about radioactive substances such as uranium and plutonium. Have them consider the exposure to radiation some people have been exposed to such as after nuclear testing or the Chernobyl accident. Why is radiation dangerous? Where does radiation come from? What effects would come from having radioactive materials in their homes? What radioactive substance might be found in their basements (radon)?

Goal

■ **Model** decay of a uranium atom.

Possible Materials

brown rice
white rice
colored candies
dried beans
dried seeds
glue
poster board

Safety Precautions

WARNING: *Never eat foods used in the lab.*

Data Source

Refer to your textbook for general information about transmutation.

Modeling Transmutations

Real-World Problem

Imagine what would happen if the oxygen atoms around you began changing into nitrogen atoms. Without oxygen, most living organisms, including people, could not live. Fortunately, more than 99.9 percent of all oxygen atoms are stable and do not decay. Usually, when an unstable nucleus decays, an alpha or beta particle is thrown out of its nucleus, and the atom becomes a new element. A uranium-238 atom, for example, will undergo eight alpha decays and six beta decays to become lead. This process of one element changing into another element is called transmutation. How could you create a model of a uranium-238 atom and the decay process it undergoes during transmutation? What types of materials could you use to represent the protons and neutrons in a U-238 nucleus? How could you use these materials to model transmutation?

Make a Model

1. **Choose** two materials of different colors or shapes for the protons and neutrons of your nucleus model. Choose a material for the negatively charged beta particle.

Differentiated Instruction

Physically Challenged If students cannot manipulate the materials, have them design a model, and ask other students to work with them to make the model.

Using Scientific Methods

- Decide** how to model the transmutation process. Will you create a new nucleus model for each new element? How will you model an alpha or beta particle leaving the nucleus?
- Create** a transmutation chart to show the results of each transmutation step of a uranium-238 atom with the identity, atomic number, and mass number of each new element formed and the type of radiation particle emitted at each step. A uranium-238 atom will undergo the following decay steps before transmuting into a lead-206 atom: alpha decay, beta decay, beta decay, alpha decay, alpha decay, alpha decay, alpha decay, alpha decay, beta decay, beta decay, alpha decay, beta decay, beta decay, alpha decay.
- Describe** your model plan and transmutation chart to your teacher and ask how they can be improved.
- Present** your plan and chart to your class. Ask classmates to suggest improvements in both.
- Construct your model of a uranium-238 nucleus showing the correct number of protons and neutrons.

Test Your Model

- Using your nucleus model, demonstrate the transmutation of a uranium-238 nucleus into a lead-206 nucleus by following the decay sequence outlined in the previous section.
- Show the emission of an alpha particle or beta particle between each transmutation step.

Analyze Your Data

- Compare** how alpha and beta decay change an atom's atomic number.
- Compare** how alpha and beta decay change the mass number of an atom.

Conclude and Apply

- Calculate** the ratio of neutrons to protons in lead-206 and uranium-238. In which nucleus is the ratio closer to 1.5?
- Identify** Alchemists living during the Middle Ages spent much time trying to turn lead into gold. Identify the decay processes needed to accomplish this task.

Communicating Your Data

Show your model to the class and explain how your model represents the transmutation of U-238 into Pb-206.

LAB 809

Assessment

Process Ask students to make pamphlets identifying ways the transmutation of uranium and plutonium are used. **nuclear power plant, nuclear weapons, nuclear submarines, and spacecraft** Use **Performance Assessment in the Science Classroom**, p. 129.

Communicating Your Data

Encourage students to use computer-generated diagrams to accompany their models.

Make a Model

Possible Procedures

- Use white rice for protons and brown rice for neutrons.
- Make a model of the nucleus of a uranium-238 atom in the upper left corner of the poster board by gluing the appropriate rice to the board.
- Draw an arrow with the type of decay above it pointing to the resulting isotope.
- Repeat all 14 steps of decay.
- Make rice model of lead-206 nucleus in lower right corner.

Teaching Strategy Have references available for students to use that show the transmutation of uranium into lead.

Test Your Model

Expected Outcome Students will build a model that demonstrates the transmutation of uranium.

Analyze Your Data

- Alpha decay decreases the atomic number by two; beta decay increases the atomic number by one.
- Alpha decay decreases the mass number by four; beta decay causes no change in the mass number.

Conclude and Apply

- For lead-206, the ratio is 1.51. For uranium-238, the ratio is 1.59. Lead-206 has a ratio closer to 1.5.
- Two alpha decays and one beta decay would be required to turn an atom of lead into an atom of gold.

Content Background

After Henri Becquerel's discovery of radioactivity in 1896, no one as yet suspected that atoms were not indivisible. At first it was thought that radioactivity was the result of chemical processes that occurred in the atoms involved. However, in 1902, Ernest Rutherford and Frederick Soddy discovered that radioactive thorium produced other elements, and realized that thorium atoms were decaying.

In the early 1930s, Enrico Fermi started a series of experiments in which he bombarded nuclei of various elements with neutrons, in an attempt to produce artificial radioactivity. When uranium was bombarded with neutrons, several radioactive products were produced. In 1938, Otto Hahn and Fritz Strassmann announced that the products of the neutron bombardment of uranium were smaller nuclei. This was the first demonstration of nuclear fission.

Historical Significance

The discovery of radioactivity and the development of methods to control nuclear fission have resulted in techniques for using nuclear radiation to treat diseases, as well as nuclear power plants. However, the development of nuclear weapons has had a profound impact on relations between the United States and other countries.

The Nuclear Alchemists

The colored tracks are alpha particles emitted from a speck of radium salt placed on a special photographic plate.

For centuries, ancient alchemists tried in vain to convert common metals into gold. However, in the early 20th century, some scientists realized there was a way to convert atoms of some elements into other elements—nuclear fission.

A Startling Discovery

As the twentieth century dawned, most scientists thought atoms could not be broken apart. In 1902, New Zealand physicist Ernest Rutherford and his colleague Frederick Soddy showed that heavy elements uranium and thorium decayed into slightly lighter elements, with the production of helium gas. "Don't call it transmutation. They'll have our heads off as alchemists!" Rutherford warned Soddy. In 1908, Rutherford showed that the alpha particles emitted in radioactive decay were the same as helium nuclei.

Something's Missing

In 1938 in Germany, Otto Hahn and Fritz Strassmann found the uranium-235 nucleus would split if struck by a neutron. The process was called nuclear fission.

Enrico Fermi led the development of the first nuclear reactor.

A year later, Austrian physicist Lise Meitner pointed out that the total mass of the particles produced when the uranium nucleus split was less than that of the original uranium nucleus. According to the special theory of relativity, this small amount of missing mass results in the release of a tremendous amount of energy when fission occurs. But is there any way this energy can be controlled?

Lise Meitner was the first to explain how nuclear fission occurs.

Controlling a Chain Reaction

Only a few years later, Italian physicist Enrico Fermi, working with colleagues in the United States, found the answer. Fermi realized that the neutrons released when fission occurs could lead to a chain reaction. However, materials that absorb neutrons could be used to control the chain reaction. In late 1942, Fermi and his colleagues built the first nuclear reactor by using cadmium rods to absorb neutrons and control the chain reaction. The tremendous energy released by nuclear fission could be controlled.

Research Find out more about the contributions these scientists made to understanding radioactivity and the nucleus. What other discoveries did Rutherford and Fermi make?

Research Rutherford also discovered alpha rays and beta rays, the existence of the atomic nucleus, and predicted the existence of the neutron. Fermi discovered that neutron bombardment causes nuclear transformations, formulated the theory of beta decay, and predicted the existence of the neutrino.

How Do We Know the Nature of the Atom?, Natalie Goldstein, Rosen Publishing Group, Incorporated, 2001

Ernest Rutherford and the Atom, John L. Heilbron, Oxford, 2003

Reviewing Main Ideas

Section 1 Radioactivity

1. The protons and neutrons in an atomic nucleus, like the one to the right, are held together by the strong force.
2. The ratio of protons to neutrons indicates whether a nucleus will be stable or unstable. Large nuclei tend to be unstable.
3. Radioactivity is the emission of energy or particles from an unstable nucleus.
4. Radioactivity was discovered accidentally by Henri Becquerel about 100 years ago.

Nucleus

Section 2 Nuclear Decay

1. Unstable nuclei can decay by emitting alpha particles, beta particles, and gamma rays.
2. Alpha particles consist of two protons and two neutrons. A beta particle is an electron.
3. Gamma rays are the highest frequency electromagnetic waves.
4. Half-life is the amount of time in which half of the nuclei of a radioactive isotope will decay.
5. Because all living things contain carbon, the radioactive isotope carbon-14 can be used to date the remains of organisms that lived during the past 50,000 years, such as this skeleton.
6. Radioactive isotopes of uranium are used to date rocks.

Section 3 Detecting Radioactivity

1. Radioactivity can be detected with a cloud chamber, a bubble chamber, an electro-scope, or a Geiger counter.
2. A Geiger counter measures the amount of radiation by producing electric current when it is struck by a charged particle.
3. Background radiation is low-level radiation emitted by naturally occurring isotopes found in Earth's rocks and soils, the atmosphere, and inside your body.

Section 4 Nuclear Reactions

1. When nuclear fission occurs, a nucleus splits into smaller nuclei. Neutrons and a large amount of energy are emitted.
2. Neutrons emitted when a nuclear fission reaction occurs can cause a chain reaction. A chain reaction can occur only if a critical mass of material is present.
3. Nuclear fusion occurs at high temperatures when light nuclei collide and form heavier nuclei, releasing a large amount of energy.
4. Radioactive tracers that are absorbed by specific organs can help diagnose health problems. Nuclear radiation is used to kill cancer cells.

FOLDABLES Use the Foldable that you made at the beginning of this chapter to help you review advantages and disadvantages of using radioactive materials and nuclear reactions.

Reviewing Main Ideas

Summary statements can be used by students to review the major concepts of the chapter.

Assessment

Nuclear Changes		
Elements		
Element name	Number of protons	Number of neutrons
Carbon	6	6
Cobalt	27	32
Iodine	53	74
Uranium	92	144

Isotopes		
Isotope name	Number of protons	Number of neutrons
Carbon-14	6	8
Cobalt-60	27	33
Iodine-131	53	78
Uranium-235	92	143

1. The element carbon has at least one other isotope, carbon-13. A reasonable hypothesis based on the data contained in the tables is that carbon-13 has
 A 8 neutrons C 6 electrons
 B 7 neutrons D 12 protons

2. What do the elements and their isotopes have in common?
 F same number of protons H same mass number
 G same number of neutrons J same nuclear mass

FOLDABLES Have students use their Foldables to review the content of the chapter. Is radioactivity necessarily a good thing or a bad thing? Explain why.

Using Vocabulary

- Both are used to detect subatomic particles. In both, charged particles create ions. In a cloud chamber, vapor condenses around these ions. In a bubble chamber, a liquid boils along the trail of ions.
- A chain reaction is an ongoing series of fission reactions. Critical mass is the minimum amount of fissionable material required for a fission chain to occur.
- Nuclear fission is the splitting of a nucleus. Nuclear fusion is the combining of two nuclei.
- Radioactivity is the emission of high-energy radiation or particles from the nucleus of a radioactive atom. Half-life is the time required for half of a sample of radioactive material to decay.
- An alpha particle is made of two protons and two neutrons. A beta particle is a high-speed electron. A gamma ray is high-energy electromagnetic radiation. All are types of nuclear radiation.
- A Geiger counter is a device that measures radioactivity by producing an electric current when radiation is present. A tracer is a radioactive isotope that can be detected as it moves in an organism.
- Nuclear fission is the splitting of a nucleus. Transmutation is the process of changing one element to another.
- An electroscope detects radiation by responding to ionization of the surrounding air, which causes its leaves to separate. In a Geiger counter, electric current is produced when the instrument detects radiation.
- The strong force binds atomic nuclei together. Radioactivity occurs when a nucleus emits alpha, beta, or gamma radiation.

Checking Concepts

10. A 13. A 16. D
11. B 14. A
12. B 15. A

SC.A.2.4.3, SC.A.2.4.4, SC.C.2.4.4

Using Vocabulary

alpha particle p.	half-life p. 794
beta particle p.	nuclear fission p. 8
bubble chamber p.	nuclear fusion p. 8
chain reaction p. 80	radioactivity p.
cloud chamber p. 79	strong force p.
critical mass p. 8	tracer p. 804
gamma ray p.	transmutation p.
Geiger counter p.	

FCAT Vocabulary

Use what you know about the vocabulary words to explain the differences in the following sets of words. Then explain how the words are related.

- cloud chamber—bubble chamber
- chain reaction—critical mass
- nuclear fission—nuclear fusion
- radioactivity—half-life
- alpha particle—beta particle—gamma ray
- Geiger counter—tracer
- nuclear fission—transmutation
- electroscope—Geiger counter
- strong force—radioactivity

Checking Concepts

Choose the word or phrase that best answers the question.

- What keeps particles in a nucleus together?
A) strong force C) electrical force
B) repulsion D) atomic glue
- Which device would be most useful for measuring the amount of radiation in a nuclear laboratory?
A) a cloud chamber
B) a Geiger counter
C) an electroscope
D) a bubble chamber

- What is an electron that is produced when a neutron decays called?
A) an alpha particle
B) a beta particle
C) gamma radiation
D) a negatron
- Which of the following describes an isotope's half-life?
A) a constant time interval
B) a varied time interval
C) an increasing time interval
D) a decreasing time interval
- For which of the following could carbon-14 dating be used?
A) a bone fragment
B) a marble column
C) dinosaur fossils
D) rocks

Use the illustration below to answer question 15.

- Which term describes an ongoing series of fission reactions such as the one pictured above?
A) chain reaction C) positron emission
B) decay reaction D) fusion reaction
- Which of the following describes atoms with the same number of protons and a different number of neutrons?
A) unstable C) radioactive
B) synthetic D) isotopes

Interpreting Graphics

17. Copy and complete the following concept map on radioactivity.

18. Make a table summarizing the use of radioactive isotopes or nuclear radiation in the following applications: radioactive dating, monitoring the thyroid gland, and treating cancer. Include a description of the radioactive isotope or radiation involved.

Use the data in the table below to answer question 19.

Isotope Half-Lives

Isotope	Mass Number	Half-Life
Radon-222	222	4 days
Thorium-234	234	24 days
Iodine-131	131	8 days
Bismuth-210	210	5 days
Polonium-210	210	138 days

19. Graph the data in the table above with the x-axis the mass number and the y-axis the half-life. Infer from your graph whether there is a relationship between the half-life and the mass number. If so, how does half-life depend on mass number?

Thinking Critically

20. Explain why the amount of background radiation a person receives can vary greatly from place to place.
21. Infer how the atomic number of a nucleus changes when the nucleus emits only gamma radiation.
22. Identify the properties of alpha particles that make them harmful to living cells.
23. Determine the type of nuclear radiation that is emitted by each of the following nuclear reactions:
- uranium-238 to thorium-234
 - boron-12 to carbon-12
 - cesium-130 to cesium-130
 - radium-226 to radon-222
24. Determine how the motion of an alpha particle is affected when it passes between a positively charged electrode and a negatively charged electrode. How is the motion of a gamma ray affected?
25. Infer how the background radiation a person receives changes when they fly in a jet airliner.

Applying Math

26. Use a Ratio The mass of an alpha particle is 4.0026 mass units, and the mass of a beta particle is 0.000548 mass units. How many times larger is the mass of an alpha particle than the mass of a beta particle?
27. Calculate Number of Half-Lives How many half-lives have elapsed when the amount of a radioactive isotope in a sample is reduced to 3.125 percent of the original amount in the sample.

Interpreting Graphics

17. Check students' work.
18. radioactive dating: carbon-14; monitoring the thyroid gland: iodine-131; treating cancer: gamma rays
19. Graphs should show that there is no relation between mass number and half-life.

Thinking Critically

20. The amount of background radiation a person receives depends on their elevation above sea level, the material their house is made from, and the type of minerals in the ground.
21. The atomic number doesn't change when gamma radiation is emitted.
22. Alpha particles have the most mass and the greatest charge, and cause more ions to be formed as they travel in matter.
23. a. alpha particle, b. beta particle, c. gamma radiation, d. alpha particle
24. The alpha particle is deflected toward the negative electrode; the gamma ray is not affected.
25. The background radiation increases, because there is less atmosphere at higher elevations to absorb cosmic rays.

Applying Math

Math Standards

National: 1, 6, 9

Florida: MA.A.1.4.4

26. about 7,300 times larger
27. five half-lives

6. C
7. D
8. B

Gridded Response

9. 10

Record your answers on the answer sheet provided by your teacher or on a sheet of paper.
The assessed Florida Benchmark appears above the question.

Multiple Choice

1. If a radioactive material has a half-life of 10 years, what fraction of the material will remain after 30 years?
 - A. one-half
 - B. one-third
 - C. one-fourth
 - D. one-eighth
2. Which of the following statements is true about all the isotopes of an element?
 - A. They have the same mass number.
 - B. They have different numbers of protons.
 - C. They have different numbers of neutrons.
 - D. They have the same number of neutrons.

SCA.2.4.3

3. How does the beta decay of a nucleus cause the nucleus to change?
 - A. The number of protons increases.
 - B. The number of neutrons increases.
 - C. The number of protons decreases.
 - D. The number of protons plus the number of neutrons decreases.

Use the illustration below to answer question 4.

4. Which is a true statement about the two nuclei?
 - A. They have the same atomic number.
 - B. They have the same mass number.
 - C. They have different numbers of electrons.
 - D. They have different numbers of protons.
5. What is the atomic number of a nucleus equal to?
 - A. the number of neutrons
 - B. the number of protons
 - C. the number of neutrons and protons
 - D. the number of neutrons minus the number of protons

Use the illustration below to answer questions 6 and 7.

SCA.2.4.3

6. What process is shown by this illustration?
 - A. nuclear fusion
 - B. chain reaction
 - C. transmutation
 - D. beta decay

Test-Taking Tip

Understand the Question Be sure you understand the question before you read the answer choices. Make special note of words like NOT or EXCEPT. Read and consider all the answer choices before you mark your answer sheet.

Short Response

10. iodine-131
11. lithium-7

Rubrics

For more help evaluating Short- and Extended-Response questions, see the rubrics on p. 97.

SC.2.A.2.4.3

7. How do the total charge and total mass number of the products compare to the charge and mass number of the polonium nucleus?
 - A. The charges are equal but the mass numbers are not equal.
 - B. The mass numbers are equal but the charges are not equal.
 - C. Neither the mass numbers or the charges are equal
 - D. The mass numbers and charges are equal.
8. Radioactive isotopes of which element are used to study the brain?
 - A. uranium
 - B. fluorine
 - C. carbon
 - D. lead

Gridded Response

Use the table below to answer questions 9 and 10.

Half-Lives of Isotopes	
Isotope	Half-life
Carbon-14	5,730 years
Potassium-40	1.28 billion years
Iodine-131	8.04 days
Radon-222	4 days

9. How many grams of an 80-g sample of carbon-14 will be left after 17,190 years?

Short Response

10. A sample containing which radioactive isotope will have one-eighth of the isotope left after 24 days?

SC.2.A.2.4.3

11. When the boron isotope boron-10 is bombarded with neutrons, it absorbs a neutron and then emits an alpha particle. Identify the isotope that is formed in this process.

INQUIRE
EXPLAIN

Extended Response

SC.2.A.2.4.3

12. Compare the strength of the strong force and the strength of the electric force on a proton in a small nucleus and in a large nucleus.

Use the illustration below to answer question 13.

13. In the figure above, nuclear radiation is escaping from a small hole in the lead box.

PART A Which type of nuclear radiation is deflected toward the positively-charged electrode, and why is this radiation deflected toward this electrode?

PART B Explain why the radiation that struck the photographic plate was not deflected by the electrodes.

Extended Response

12. Compared to a small nucleus, in a large nucleus the repulsive electric force on a proton has increased more than the attractive strong force has increased.

13. *Sample answer:*

Part A: The Beta particles are negatively charged, and because like charges repel and unlike charges attract, they are deflected away from the negatively charged electrode and toward the positively charged electrode.

Part B: Gamma rays have no charge and their motion is not affected by the charged electrodes.

Section/Objectives	Standards		Labs/Features

Section Focus

Section Focus Transparency Very Large Telescope Chapter 26

Two telescopes consist of a system of four separate optical telescopes, each 4.2 meters in diameter, mounted on a single structure. The telescopes are located on a mountain in Chile, and they observe the sky in the infrared and visible light regions.

What are the advantages of using large telescopes?

What are the disadvantages of using large telescopes?

L2

Section Focus Transparency Messier Nebula Chapter 26

The bright object is the star Messier. The nebula is called a reflecting nebula.

L2

Section Focus Transparency Coma Cluster Chapter 26

The Coma cluster is a rich cluster of galaxies with over a thousand galaxies in total. The central region is dominated by two giant galaxies.

L2

Section Focus Transparency Northern and Southern Sky Chapter 26

This panoramic view of the entire sky was made from 13 wide-angle images.

L2

This is a representation of key blackline masters available in the Teacher Classroom Resources. See Resource Manager boxes within the chapter for additional information.

Key to Teaching Strategies

The following designations will help you decide which activities are appropriate for your students.

- L1** Level 1 activities should be appropriate for students with learning difficulties.
- L2** Level 2 activities should be within the ability range of all students.
- L3** Level 3 activities are designed for above-average students.
- ELL** ELL activities should be within the ability range of English Language Learners.
- COOP LEARN** Cooperative Learning activities are designed for small group work.
- MS** Multiple Learning Styles logos, as described on page 12T, are used throughout to indicate strategies that address different learning styles.
- P** These strategies represent student products that can be placed into a best-work portfolio.
- PBL** Problem-Based Learning activities apply real-world situations to learning.

Science Content Background

Observing the Universe

Optical Telescopes

In addition to magnifying power, there are two other powers that are important to consider when selecting a telescope. The light gathering power (B) is a measure of how much light an objective lens can concentrate into the image. It is based on the aperture (diameter) of the objective lens or mirror and is also affected by the focal length of the telescope. In general, the light gathering power increases with the square of the objective's aperture. The equation for B is $B = c(a/f_o)^2$.

The resolving power (α) of a telescope is the ability to separate objects which are very close together. It is a measure of the resolution of the image or fineness of detail. The smaller the value of resolving power, the better it is. Resolving power increases with an increase in aperture. The equation for α is $\alpha = 11.6/a$ when a is in cm.

Evolution of Stars

The Sun

The *Solar and Heliospheric Observatory (SOHO)* observes the Sun 24 hours a day from a position about 1.5 million km closer to the Sun than Earth. It studies the Sun's surface, atmosphere, and interior. Some observations indicate that the Sun goes through measurable changes prior to ejecting material through coronal storms. If these storms can be predicted, humans can prepare for the disruption of communication, power generation, and electronics. SOHO has helped scientists determine that the boundary between the convection zone and radiation zone is located 71.3 percent outward from the Sun's center.

Galaxies and the Milky Way

Galaxy Center

Studies of other galaxies indicate the possibility that massive black holes exist at galactic centers. In these studies,

radio telescopes were connected across an entire continent, drastically increasing the telescopes' resolving power. When aimed at nearby galaxy M106, data indicated the existence of a disk of gas with properties consistent with the existence of a black hole equal in mass to 36 million suns.

Cosmology

Dark Energy

In a universe with accelerating expansion, the redshifts of distant objects are less than would be expected. Using Type I supernovas as a standard, scientists determine their distance independent of redshift values. Then by comparing distance to the redshift of the light from these supernovas, scientists have calculated a rate of expansion in the past that is lower than the expected value. This means that the expansion of the universe is accelerating. It is not known what is causing this, but it is neither matter nor radiation. The accelerating expansion is caused by an unknown type of energy called dark energy. Because gravity weakens as matter becomes farther apart, dark energy might eventually dominate the universe and keep it expanding forever.

IDENTIFYING

Misconceptions

Find Out What Students Think

Students may think that . . .

Stars within a constellation must be close to one another in space.

Students might not be aware that stars can be very far away from each other and still appear to be side by side. Also, they might think that brighter stars are closer and that if two stars that appear to be side by side have the same brightness, they must be close to each other. These misconceptions come about because of the lack of depth perception when looking at stars in the sky and because the stars in a constellation are connected by mythology.

Discussion

Organize the class into groups and have each group work together to research the distance to several stars in a well-known constellation, such as Orion. **Possible answer: Betelgeuse is 427 light-years, Bellatrix is 243 light-years, Rigel is 773 light-years, the three stars that form the belt are about 1,025 light-years, and Meissa, Salph, and Na'ir al Saif are about 1,025 light-years from Earth.**

Promote Understanding

Demonstration

- Take students to a large, open room, such as the gym or cafeteria or outside if weather permits.
- Have most of the students stand at random locations in the room or on the grass outside the school.
- Have a student close one eye and look across the room or field and note that two or three people

can look as if they are standing next each other, but are actually different distances away.

- Relate the appearance of people standing in widely separated positions appearing to be side by side to the fact that stars within a constellation can be separated by a great distance and still appear to be side by side.

Assess

After completing the chapter, see *Identifying Misconceptions* in the Study Guide at the end of the chapter.

Colliding Galaxies

These two spiral galaxies, known as “the mice,” have been colliding for about 160 million years. Eventually, they will merge into one giant, elliptical galaxy.

Science Journal In your Science Journal, write a paragraph about what you know about the Sun as a star.

816

Theme Connection

Scale and Structure and Stability and Change Two themes are involved in this chapter. One pertains to the immense scale of space and the overall structure of the universe. The second pertains to the apparent stability of the universe when viewed over a short span of time and the gradual changes of stars, galaxies, and the universe when viewed over the total time the universe has been in existence.

About the Photo

Colliding Galaxies This *Hubble* photo is a mosaic of four filtered images combined to approximate natural color. Orange areas are cores of the two galaxies. A band of dark dust lies between the cores and dust filaments criss-cross the areas where bright, blue star clusters are forming. In some areas, dust scatters the blue light, making it appear reddish.

Start-Up Activities

Stars in the Sky

Have you ever looked up at the night sky and been amazed at the number of stars you could see? But if you live in a well lighted area, you may not have seen very many stars at all. In this lab, you will explore a quick way to estimate how many stars you can see in different parts of the sky.

1. Ask an adult to help you locate an area near your home suitable for star gazing where there are not very many lights.
2. Hold a cardboard tube up to one eye and look through it at one area of the sky.
3. Count the number of stars you can see easily through the tube.
4. Look at three other areas of the sky in the same way and count those stars. Try looking to the south, west, straight up, and in a random direction.
5. Compare your data with those of two or three other students.
6. **Think Critically** In your Science Journal, report whether a similar number of stars were easily visible no matter where you looked or whether the number of stars varied. Explain any similarities or differences noted by you or other students.

FOLDABLES Study Organizer

Cosmology Make the following Foldable to help identify what you know, what you want to know, and what you learned about stars, galaxies, and cosmology.

STEP 1 Fold a vertical sheet of paper from side to side. Make the front edge about $\frac{1}{2}$ inch longer than the back edge.

STEP 2 Turn lengthwise and fold into thirds.

STEP 3 Unfold and cut only the top layer along both folds to make three tabs. Label each tab as shown.

Questioning Before you read the chapter, write what you know about cosmology under the left tab of your Foldable, and write questions about what you'd like to know under the center tab. After you read the chapter, list what you learned under the right tab.

Science online

Preview this chapter's content and activities at www.ck12.org

Purpose Use this Launch Lab to introduce students to the number of stars that are visible in different areas of the sky. **L2** **IS** **Kinesthetic**

Preparation Obtain several cardboard tubes from empty rolls of paper towels.

Materials cardboard tubes

Alternative Materials rolled-up construction paper

Teaching Strategy Use a cardboard tube and look in different directions in the classroom to demonstrate observations of the sky.

Safety Precaution Caution students to use the cardboard tube carefully when viewing.

Think Critically

Student answers should indicate that the numbers of stars visible in different areas varies. Possible answer: Stars are visible in every direction, but more stars are visible in some areas than in others.

Assessment

Oral Are the number of stars visible in different parts of the sky the same? Explain. Possible answers: No, some areas of the sky appear to have more stars. This is caused by comparing observations in the direction of the rim of our galaxy's disk (the Milky Way) to areas above or below it.

Tie to Prior Knowledge

Constellations Ask students if they have seen any constellations in the night sky. Ask if they could recognize the patterns of stars that comprise Orion the hunter or the Big Dipper. Ask a volunteer to draw on the chalkboard any familiar constellation. L2

Graphic Organizer On the board draw a hierarchical chart for Telescopes. Create three levels with the following words in boxes, connected with lines to show their relationships. Top level: *Telescopes* Second level: *Optical Telescopes/Radio Telescopes/Space Telescopes* Third level under Optical: *Reflecting Telescopes/Refracting Telescopes*

Reading Guide

What You'll Learn

- **Describe** a constellation as a pattern of stars.
- **Compare and contrast** types of optical telescopes.
- **Explain** how a radio telescope differs from an optical one.

Why It's Important

You can observe different parts of the universe from your home.

Review Vocabulary

electromagnetic spectrum: the entire range of wavelengths of electromagnetic energy

New Vocabulary

- constellation
- refracting telescope
- reflecting telescope
- radio telescope
- light-year
- spectroscope

Constellations

Have you ever watched clouds drift by on a summer day and tried to find shapes and patterns in them? One might look like a ship and another might resemble a rabbit or a bear. Long ago, people did much the same thing with stars. They named these patterns of stars after characters in stories, animals, or tools. Many of the names given to these star patterns by ancient cultures survive today and are called **constellations**. Astronomers use these constellations to locate and name stars.

From Earth, the stars in a constellation appear relatively close to one another. You can see that some of the stars are brighter than others, but you can't see how far they are from you or from each other. Usually, they lie at greatly different distances and just happen to line up and form a pattern.

In **Figure 1**, three constellations are shown with some of their brighter stars. The constellations visible in the evening sky change throughout the year.

Figure 1 These three constellations contain some of the brightest stars visible from the northern hemisphere—Betelgeuse, Rigel, and Sirius.

Mythology

In many cultures, Orion was a great hunter who had two hunting dogs, Canis Major (big dog) and Canis Minor (little dog). In another myth, two bears traveled around Earth's north pole. The constellations Ursa Major and Ursa Minor (big and little bears) were named for them. Indeed, they do swing around the north pole. In fact, Polaris, the polestar, is in Ursa Minor. If you have seen the Big Dipper you have seen most of Ursa Major, because the dipper is part of this constellation.

Telescopes Constellations and the stars that make them up are visible with the unaided eye. However, to see other objects in space, or to see some objects better, you need a telescope. Scientists and amateur astronomers use many different types of telescopes. Optical telescopes are used to study objects in visible light, and radio telescopes are used to study objects in the radio wavelengths. What do you think would be used to study X rays?

Optical Telescopes There are two basic types of optical telescopes. One type uses only lenses to study light and the other uses lenses and mirrors. Optical telescopes collect visible light and produce magnified images of objects. Light is collected by an objective lens or mirror. Because starlight is so distant, the light forms an image at the focus of the telescope. The focus is where light that is bent by the objective lens or reflected by the objective mirror comes together. A second lens, the eyepiece lens, then magnifies the image. The distance from the objective to the focus is the focal length of the telescope. You can find the magnifying power (M_p) of a telescope by dividing the focal length of the objective (f_o) by the focal length of the eyepiece (f_e).

$$M_p = f_o / f_e$$

Refracting Optical Telescopes A **refracting telescope** uses a convex lens, which is curved outward like the surface of a ball, as an objective, shown in **Figure 2**. When the lens curves outward on both sides, it is a double convex lens. Light passes through the objective lens. The eyepiece, which also can be a double convex lens, then magnifies the image. There is a limit to how large a refracting telescope can be. Since the objective lens can be supported only at its edges, it could sag in the middle if it is too large. When a larger telescope is needed, a reflecting telescope is used.

Reading Check What type of optical telescope uses a lens as an objective?

Figure 2 Two lenses are all that is needed for a refracting telescope. The tube and tripod aid in viewing.

Identify the curvature of an objective lens.

SECTION 1 Observing the Universe 819

Differentiated Instruction

English-Language Learners Help your English-language learners by showing them photographs and drawings of refracting telescopes. Encourage them to build the telescope and to see if it works. Provide drawings of how to determine the focal lengths of the two lenses and help them fit the two sections of their telescopes together.

Reading Strategy

Determine Importance Have students copy the hierarchical chart for telescopes that was used to introduce the vocabulary words. Then, as they read the text, have them determine the important details for each type of telescope and add these to their chart.

Mini LAB

Modeling a Telescope

Procedure

1. Obtain two lenses of different focal length from your teacher.
2. Place **double-sided tape** around the edge of one lens.
3. Place the lens along the short side of a piece of **construction paper** and roll the paper around the lens to form a tube. Tape the tube securely.
4. Repeat steps 2 and 3 with the other lens.
5. Insert the small tube into the large tube with the lenses on opposite ends.
6. Look through the eyepiece lens (small tube) and slide it in and out until you see a clear image.

Analysis

1. Observe an object with and without your telescope. Estimate how many times larger it appears through the telescope.
2. Obtain the focal lengths of your lenses from your teacher. Calculate the magnifying power of your telescope using the equation on this page. Compare this value to your estimate.

Test Question Answer

X-ray telescope

2 Teach

Mini LAB

Purpose Students will design and build a telescope. Students will then observe objects and calculate the magnifying power of their telescopes by solving a one-step equation. **L2 LS Kinesthetic**

Materials construction paper, two lenses of different focal lengths, tape, double-sided tape

Teaching Strategy Construct a telescope prior to students' attempts.

Safety Precautions

- Caution students to handle lenses with care and not to use broken or chipped ones.
- Students should wear eye protection.

Analysis

1. Lenses with focal lengths of 30 mm and 5 mm should make objects look six times larger.
2. If the actual magnifying power is six, an estimate of four should be considered close enough.

Assessment

Performance Ask students to determine the focal length needed for an objective lens if the eyepiece focal length is 6 mm and you want a magnifying power of 150. **Possible answer:** 900 mm Use PASC, p 101. **L2 Logical—Mathematical**

Reading Check

Answer refracting

Quick Demo

Image Formation

Materials a glass, 15-cm focal length lens

Estimated Time 5 minutes

Procedure Darken the room so that the only light comes in the window. Have a student hold up a sheet of white paper so students can see it. Use the lens to demonstrate how an image is formed. Hold the lens up to the window so that light coming in the window falls on the sheet of paper and forms an image. Explain that the lens is like the objective of a telescope. **L2 ELL Visual-Spatial**

Applying Math

Math Standards

National: 1, 9

Florida: MA.A.3.4.1

Teaching Strategies

- Place a simple equation on the chalkboard ($a = 2b$). Tell students the value of b is 12. Rewrite the equation as $a = 2 \times 12$. Ask students to solve the equation for a . **Answer:** 24
- Now write another simple equation on the chalkboard $a = b/c$. Tell them the value of b is 10 and the value of c is 5. Rewrite the equation as $a = 10/5$. Ask them to solve the equation for a . **Answer:** 2
- Relate these simple example equations to the one for the magnifying power of a telescope.

Answers to Practice Problems

- $M_p = 2500 \text{ mm}/50 \text{ mm} = 50$;
 $M_p = 2500 \text{ mm}/10 \text{ mm} = 250$
- $M_p = 900 \text{ mm}/12 \text{ mm} = 75$

Figure 3 Reflecting telescopes use concave mirrors to gather light.

Reflecting Optical Telescopes A reflecting telescope uses a mirror as an objective to reflect light to the focus. **Figure 3** shows how light passes through the open end of a reflecting telescope and strikes a concave mirror at the base of the telescope. Often, a smaller mirror is used to reflect light into the eyepiece where it is magnified for viewing. However, in very large reflecting telescopes, the astronomer sits inside the telescope and looks through the eyepiece at the focus. Because mirrors can be supported from underneath a much larger telescope can be built.

Applying Math

Use Equations

THE MAGNIFYING POWER OF TELESCOPES If the focal lengths of a telescope's objective and eyepiece are known, the magnifying power can be calculated from the equation:

$$M_p = f_o / f_e$$

In this equation, M_p is the magnifying power of the telescope, f_o is the focal length of the objective, and f_e is the focal length of the eyepiece. Find the magnifying power of a telescope with a focal length of 1200 mm using eyepieces of 20 mm and 6 mm.

IDENTIFY known values and unknown values.

Identify the known values.

the focal length of the objective is 1,200 mm, this means $f_o = 1,200 \text{ mm}$

the focal lengths of the eyepieces are 20 mm and 6 mm, this means $f_e = 20 \text{ mm}; 6 \text{ mm}$

Identify the unknown value

what is the magnifying power of the telescope means $M_p = ?$

SOLVE the problem

Substitute the known values into the equation for magnifying power:

$$M_p = 1,200 \text{ mm}/20 \text{ mm} = 60 \quad M_p = 1,200 \text{ mm}/6 \text{ mm} = 200$$

Notice that the units cancel, and that magnifying power has no unit.

CHECK the answer

Does your answer seem reasonable? Do images look 60 times larger than the object when using the 20 mm eyepiece and 200 times larger when using the 6 mm eyepiece?

Practice Problems

- Find the magnifying power of a telescope with a focal length of 2,500 mm when using eyepieces with focal lengths of 50 mm and 10 mm.
- Find the magnifying power for a telescope with a focal length of 900 mm when using an eyepiece with a focal length of 12 mm.

Teacher FYI

The Hubble Space Telescope The *Hubble Space Telescope* is a reflecting telescope with an objective mirror 240 cm in diameter. It is in orbit 610 km above the Earth's surface. Radio emissions send commands to the telescope and send images taken by the *Hubble Space Telescope* back to Earth.

New Telescope Design The most recent innovations in optical telescopes involve active and adaptive optics. With active optics, a computer is used to correct changes in temperature, mirror distortions, and bad viewing conditions. Adaptive optics uses a laser to probe the atmosphere and relay information to a computer about air turbulence. The computer then adjusts the telescope's mirror thousands of times per second to lessen the effects of atmospheric turbulence. The European Southern Observatory's *Very Large Telescope* in Chile, the largest optical telescope in use, uses adaptive optics.

Radio Telescopes Radio waves, like visible light, are a form of electromagnetic energy emitted by stars and other objects in space. Radio waves can be detected even during the day, when the Sun's light makes it impossible to see the fainter visible light from other stars. Radio waves pass freely through Earth's atmosphere, even on completely cloudy days.

A telescope that collects and amplifies radio waves is a **radio telescope**. Because radio waves have long wavelengths, a radio telescope must be built with a very large objective, usually some form of dish antenna. Astronomers often build several radio telescopes close together and connect them to form one large telescope. The VLA (very large array), shown in **Figure 4**, is an example of this.

Reading Check What type of telescope is used to study radio waves?

Hubble Space Telescope Even using active and adaptive optics, the atmosphere limits what Earth-based telescopes can achieve. For this reason, astronomers use space telescopes, such as the *Hubble Space Telescope* shown in **Figure 5**.

The clear images provided by *Hubble* are changing scientists' ideas about space. One object viewed by *Hubble* is the massive galaxy cluster Abell 2218, which is about 2 billion light-years away. This cluster acts as a gravity lens that magnifies the light of even more distant galaxies. Such large distances in space are measured in a unit called a **light-year**, the distance that light travels in one year—about 9.5 trillion km. Even though it may seem confusing, remember that a light-year measures distance, not time.

Visual Learning

Figure 5 Help students understand the information shown in **Figure 5**. Point out where the objective mirror is located on the *Hubble Space Telescope*. Show students the solar panels that provide power to the telescope in orbit. Explain that several teams of astronauts have visited the *Hubble Space Telescope* in the Space Shuttle and that astronauts have repaired and updated the satellite telescope. **L2**

ELL **AS** Visual-Spatial

Science Journal

What have we learned? Have students write an article for a newspaper in their Science Journals about some of the discoveries that have been made and are still being made by the *Hubble Space Telescope*. Possible answer: photographs of some of the dimmest galaxies ever seen, photographs of galaxy interactions, photographs of Pluto and Charon. **L1** **AS** Linguistic

Topic: New Telescope Design

Visit fl.gpescience.com for Web links to information about the development of new telescopes.

Activity Write and illustrate a paragraph about one of the new designs being considered for Earth-based telescopes or Earth-orbital telescopes.

Figure 5 The *Hubble Space Telescope* orbits Earth at an altitude of 610 km.

SECTION 1 Observing the Universe 821

Activity

View Through a Telescope Provide students with two lenses (one with a 30-mm focal length and one with a 10-mm focal length). Have students hold the thicker lens (the 10-mm focal length lens) up to their eyes and place the other lens directly in line with the first but farther from their eyes. Have students move the lenses back and forth until they can see an image clearly. Ask them to write a description of what they see in their Science Journals. **Students should see that the image is reversed and inverted. They should note that objects appear about three times larger and that a tube is not needed to have a telescope.**

L2 **ELL** **AS** Visual-Spatial

Reading Check

Answer radio telescope.

Discussion

Light Pollution One problem amateur astronomers have with observing from their homes is light pollution. Light from homes, street lights, malls, and city lights make observing almost impossible. Ask students to research the problem of light pollution and then have them discuss possible solutions to the problem. **Homeowners could turn off security lights when requested by a neighbor who wants to observe. Hoods can be placed on lights so they only shine downward. Certain light bulbs can be used that give off just a few wavelengths of light.** **L2**

Post Reading

Extended Research Have students look up information and read about the newest developments in space telescopes. As a class, have students brainstorm questions of interest such as these: What is the history and future of the *Hubble Telescope*? How many space telescopes are currently in use? Do other countries have space telescopes?

✓ Reading Check

Answer A spectroscope disperses the light into a spectrum.

Caption Answer

Figure 6 It disperses light into individual wavelengths.

3 Assess

DAILY INTERVENTION

Check for Understanding

Visual-Spatial Have students collect images of different types of telescopes and bring them to class. Separate the class into groups of four or five and have each group compile a photographic journal of the different types of telescopes. Students can separate the journal into sections with a basic diagram of the type of telescope shown in that section illustrated on the title page. Each photograph could also have a caption, in which the telescope is named and described. [L2]

Reteach

Light Years Away Place images of five different space objects on the chalkboard and label the distance to each object in light-years. Ask students when the light from each object started toward Earth. [L1]

✓ Assessment

Process Provide students with models of the two basic types of optical telescopes. Have them describe which type is more appropriate for building a large optical telescope and have them explain why. Possible answer: Reflecting, because the large objective mirror can be supported from the bottom. PASC, p. 89. [L3]

Figure 6 The dark lines in stellar spectra tell astronomers what elements are present in the stars being studied.

Explain how a spectroscope produces a spectrum of colors.

✓ Reading Check

What does a spectroscope do?

Spectra A spectroscope disperses light into its individual wavelengths, or its spectrum. Visible light yields a spectrum of colors, including red, orange, yellow, green, blue, indigo, and violet, the colors of a rainbow. In fact, a rainbow is actually a visible spectrum of sunlight that has been dispersed by droplets of water in Earth's atmosphere. A spectrum displays all wavelengths in the light being studied, shown in **Figure 6**. You have learned that a star's spectrum indicates its surface temperature. For example, if the blue section is brightest, the star has a relatively high surface temperature. If the red section is brightest, the temperature of the star is much lower.

section 1 review

Summary

Constellations

- Constellations are patterns of stars that are used today to name and locate stars.

Telescopes

- Refracting telescopes use lenses to collect light and magnify the image.
- Reflecting telescopes use a mirror to collect light and a lens to magnify the image.
- A radio telescope collects and amplifies radio waves.

Spectroscopes

- A spectroscope disperses light into its spectrum.

Self Check

1. **Define** constellation.
2. **Compare and contrast** refractor telescopes and reflector telescopes.
3. **Describe** the objective of a radio telescope.
4. **Explain** how radio waves differ from visible light.
5. **Think Critically** Why do astronomers change eyepieces rather than objectives when they wish to increase the magnifying power of a telescope?

Applying Math

6. **Use Numbers** If the magnifying powers (M_p) of refracting and reflecting telescopes are 20 and 100, respectively, how much greater is the M_p of the reflecting telescope?

section 1 review

1. a pattern of stars that resembles a recognizable object, person, or animal.
2. Both are optical telescopes. Refractor telescopes use an objective lens; reflectors use an objective mirror.
3. a large dish antenna
4. They have a much longer wavelength.
5. It is easy to take out one eyepiece and replace it with another. In order to change an objective, an entirely different telescope must be used.

6. five times greater

MA.A.3.4.1

Evolution of Stars

Reading Guide

What You'll Learn

- **Explain** how stars form.
- **Classify** the stages of stellar evolution using a Hertzsprung-Russell (H-R) diagram.
- **Describe** the Sun and explain how it has and will evolve.

Why It's Important

The Sun is the star that provides energy for life on Earth.

Review Vocabulary

absolute magnitude: a measure of the amount of light given off by a star

New Vocabulary

- main sequence
- giant
- white dwarf
- **solar mass**
- photosphere
- sunspots

ICAT Vocabulary

How do stars form?

Star formation begins with condensation of a large cloud of gas, ice, and dust called a nebula. These particles exert a gravitational force on each other, and the nebula contracts. Gravitational instability within the nebula causes it to break up into smaller cloud fragments. As a cloud fragment condenses its temperature increases. When the interior temperature reaches 1 million K, the center of the cloud is called a protostar. When the temperature reaches 10 million K, hydrogen fuses to form helium and a star is born.

H-R Diagram In the early 1900s, Ejnar Hertzsprung and Henry Russell studied the relationship between absolute magnitude and temperature of stars. They noticed that higher-temperature stars radiate more energy and have higher absolute magnitudes. As stars form, even while they are still protostars, they can be plotted on the Hertzsprung-Russell (H-R) diagram, like the one shown in **Figure 7**. About 90 percent of all stars fall on a line drawn from the upper left to the lower right of the H-R diagram, called the **main sequence**. The other 10 percent of stars fall elsewhere on the graph and will be discussed later.

Figure 7 The Sun is located in the center of the main sequence on this H-R diagram. It is cooler than young stars like Vega and Sirius, but warmer than the giant Betelgeuse.

Reading Check

Answer main sequence

Purpose Students will model counting stars in the sky. **L2** **IS**
Kinesthetic

Materials blue construction paper, metric ruler, 1 tablespoon of rice kernels

Teaching Strategy Prepare a transparency of the grid students will draw. Randomly make dark marks on the grid and show students how to evaluate the total number of dots.

Analysis

1. Answers will vary, but should equal the total number counted in three squares divided by 3 and then multiplied by 20.
2. Students should realize that they could count the number of stars observed through a cardboard tube over several sections of the sky of a known area, obtain an average, and multiply it by the total area of the sky.

Assessment

Oral Ask students to propose a more accurate method. Possible answer: Several teams of students could use one of the grids and count the number of rice kernels in different grid sections. They could then average all of the counted grids from the several teams and multiply this value by 20.

Counting Stars

Procedure

1. Draw a grid of twenty squares, with each square measuring 5 cm on a side. The final grid will be 25 cm long and 20 cm wide.
2. Randomly scatter about one **tablespoon** of **white rice** over the grid.
3. Select three squares and count the number of rice grains that are either completely within each square or partly touching its right side or bottom. Calculate the average number in each square.
4. Multiply the average by 20.

Analysis

1. How many rice grains are located within the grid?
2. How does this process model counting stars?

How do stars change?

A star like our Sun probably had a diameter about 100 times its present size while a protostar. As a star continues to form, it shrinks and increases in density, raising its interior temperature. Once fusion begins and the star attains stellar equilibrium, it settles onto the main sequence. In general, stellar equilibrium is the balance between outward pressure due to energy released in fusion and inward pressure due to gravity. Once this state of equilibrium is lost, the star enters the next stage of its life.

Main Sequence As long as the star's gravity balances outward pressures, the star remains on the main sequence. Stars are thought to spend most of their lives on the main sequence, which explains why this is the largest group on the H-R diagram. The Sun has been a main sequence star for about 5 billion years and will continue in this stage for about another 5 billion years.

Reading Check The Sun is classified as which type of star?

When its hydrogen fuel is depleted, a star loses its equilibrium and its main sequence status. What it becomes next is determined by the total mass of the star. An average star like the Sun will become a giant, then a white dwarf, and finally a black dwarf. Stars more massive than the Sun can become supergiants and end up as neutron stars or black holes. Stars much lower in mass than the Sun, like the red dwarf star *Proxima Centauri*, could remain on the main sequence for 16 trillion years. Most stars on the main sequence are red dwarfs, and they probably make up about 80 percent of all stars in the universe.

Figure 8 Only part of the giant star Antares is shown here. Super giant stars, such as Betelgeuse, are too large to be shown at all.

824 CHAPTER 26 Stars and Galaxies

Visual Learning

Figure 8 Help students understand the information presented in **Figure 8**. The relative sizes of several stars are shown to scale in this illustration. Point out that white dwarf stars are very hot, but they are so small that they are difficult to see in the sky. Although they are cool, giants emit light from such a large area that they look bright even from great distances. **L2** **ELL** **IS** **Visual-Spatial**

Science Journal

Main Sequence Stars Have students write a brief summary about three hypothetical protostars having solar masses of 15, 1, and 0.1. Ask students where they would place these stars on the main sequence, and predict the relative length of time each will stay there. Possible answer: 15—upper left (will stay shortest time), 1—middle, and 0.1—lower right (will stay longest time) **L2** **IS** **Linguistic**

Giants and Dwarfs When hydrogen in a star's core is used up, its outward pressure is overcome by gravity. Its core contracts and increases in temperature. The outer layers expand and cool. In this late stage of its life cycle, an average star like our Sun is called a **giant**. In about five billion years, our Sun will become a giant like the one shown in **Figure 8**.

The giant's core continues to contract and become hotter. Eventually, the core uses up its helium and contracts even more. When temperature reaches 100 million K, helium fuses, forming carbon. Now the star is enormous and its surface is much cooler. Its outer layers escape into space leaving behind the hot, dense core that continues to contract. At this final stage in an average star's evolution, it is a **white dwarf**. A white dwarf, also shown in **Figure 8**, is about the size of Earth.

Supergiants, Neutron Stars, and Black Holes Stars that are over eight times more massive than our Sun take a different course. Their cores reach temperatures high enough to cause fusion that produces heavier and heavier elements. The star expands into a supergiant, such as Betelgeuse shown in **Figure 9**. Eventually, iron accumulates in the core. Since iron does not fuse readily, there is no outward radiation of energy to counteract the inward pull of gravity. The core collapses violently, and the outer portion of the star explodes, producing a supernova.

A supernova is a gigantic explosion in which the temperature in the collapsing core reaches 10 billion K and atomic nuclei are split into neutrons and protons. Protons merge with electrons to form neutrons, and the collapsing core becomes a neutron star. A typical neutron star is the size of a major city on Earth, but has a mass greater than the Sun's.

Very massive stars, with masses greater than 25 times that of the Sun, face a different end. In this case, the final collapse of the core continues past the neutron-star stage, forming a black hole—an object so dense that nothing can escape its gravity if it gets too close.

Supernovas The heavy elements you are made of formed during supernova explosions. Type I supernovas form from hydrogen-poor, low mass stars that have pulled in matter from a nearby red giant star. This process, called carbon detonation, causes carbon fusion almost everywhere inside the star and is thought to destroy the star completely. In contrast, Type II supernovas form from hydrogen-rich, high mass stars. They leave behind a collapsed core that can then condense further to form a neutron star or black hole.

Teacher FYI

Black Holes Contrary to what some people think, a black hole does not suck in matter from all directions. Only objects closer to the black hole than a certain point, called the event horizon, are undetectable, because no mass or radiation can escape.

Figure 9 Betelgeuse is located in the constellation of Orion. Its diameter is larger than the diameter of Jupiter's orbit around the Sun.

Classify What kind of star is Betelgeuse?

SECTION 2 Evolution of Stars 825

Activity

Giants Betelgeuse is 630, Antares is 500, Aldebaran is 40, and Sirius A is 2 times larger than the Sun. Have students use construction paper to draw and cut out representative circles for each of these stars and the Sun. Ask students to speculate on whether these stars are supergiants, giants, or main sequence stars. **Possible answer:** Betelgeuse is a supergiant, Antares and Aldebaran are giants, Sirius A and the Sun are main sequence stars. **L1 ELL**

Visual-Spatial

Caption Answer

Figure 9 supergiant

Use Science Words

Word Meaning When a star suddenly brightens by thousands or even millions of times, it is called a nova or a supernova. Ask students to research the meaning of the word *nova* and to discover why it is used when talking about stars that suddenly get brighter. **Possible answer:** Since many of these stars were not seen before they became so bright, early astronomers thought they might be a new star. "Nova" means new and is used to describe these "new" stars. **L1**

Discussion

Supernovas Have students research the cause of Type I supernovas. Ask students to discuss the processes that are involved in the formation of this type of supernova. **Possible answer:** If a white dwarf pulls too much material from its companion star, it contracts and heats up to a temperature at which carbon fuses into more massive atoms. This fusion occurs through out the star and the star explodes. **L2**

Active Reading

Quickwrites This strategy lets students use spontaneous writing to discover what they already know. Have students write a list of ideas about black holes, then share these ideas with the class. Next, have students write their ideas freely in a paragraph without worrying about punctuation, spelling, and grammar.

Reading Strategy

Sequence As they read the following pages, have students write the steps in the evolution of giant stars and supergiant stars. Ask them to identify the names of phases and the cause of each change in their evolution.

Visualizing H-R Diagrams of Star Clusters

Have students examine the pictures and read the captions. Then ask the following questions.

Compare the brightness, temperature, and age of stars in the upper right and left corners of the H-R diagram for the Pleiades. **Possible answer:** Stars in the upper right corner are cooler and older than stars in the upper left corner. Stars in both corners are relatively bright stars.

Compare the H-R diagrams of the Pleiades and M5. What major differences can you identify? **Possible answer:** The H-R diagram for M5 shows red giants and white dwarfs. It has no hot, blue stars, and lacks a well-defined main sequence.

How can the age of globular clusters like M5 help astronomers estimate the age of the universe? **Possible answer:** Globular clusters contain some of the oldest stars in the galaxy. The universe must be at least as old as these stars.

Activity

View the Pleiades The Pleiades is located in the constellation Taurus. Have students find the Pleiades in the night sky by facing south, then looking above and to the right of the constellation Orion. The first bright star they will see is Aldebaran in Taurus. The Pleiades are just up and to the right. Viewing conditions affect the number of visible stars, but students should see the brightest stars, which are Alcyone, Merope, Maia, and Electra. Students should describe their observations using a written format of their choice and include a drawing of what they saw. **P**

Figure 10

The Pleiades star cluster blazed into existence a mere 100 million years ago, when dinosaurs reigned on Earth and mammals were just gaining a foothold. The Pleiades, located in the back of the constellation Taurus, is among the earliest of celestial objects to be known and recorded by humans. Many myths sprang up to explain their origin. Today, astronomers study star clusters like the Pleiades because they offer valuable insights into how the universe is evolving.

Pleiades

Because star clusters are believed to have formed from the same nebula, they are assumed to be about the same distance away. For this reason they are plotted using apparent magnitude instead of absolute magnitude or luminosity. Note that a lower magnitude number represents a brighter star. The H-R diagram for the Pleiades shows a well-defined main sequence. Stars in the upper left are hot, blue, and massive. As stars age, they burn all available hydrogen and eventually become red giants. The presence of hot, blue stars and the lack of red giants indicate that the Pleiades is a relatively young star cluster.

M5 Globular Cluster

M5 is a globular cluster, located roughly 24,500 light-years from Earth. It has a compact appearance and vastly more stars than are found in open clusters like the Pleiades.

Astronomers believe M5 is one of the oldest star clusters in our galaxy, with an estimated age of 13 billion years.

Compare the H-R diagram for M5 to the H-R diagram for the Pleiades. The stars in cluster M5, which were once hot and blue, have evolved into cooler, highly luminous red giants that appear in the upper right of the diagram. Sun-sized stars evolve from main sequence to red giants over billions of years, indicating that M5 is an ancient star cluster.

Differentiated Instruction

Challenge Astronomers recently discovered brown dwarfs within the Pleiades star cluster. Have students research these unique objects. Students should discover the characteristics of brown dwarfs, why they are difficult to find, and how they

differ from both stars and gas planets. Have students create a chart comparing the characteristics of brown dwarfs, main sequence stars, red giants, and white dwarfs, including relative diameter, temperature, luminosity, and mass. **P**

The Sun—A Main Sequence Star

The Sun is a middle-aged star and is plotted just about in the middle of the main sequence on the H-R diagram. It is average in size, temperature, and absolute magnitude. A **solar mass** is simply the mass of the Sun. For most stars, the relationship between mass and luminosity can be approximated by

$$\frac{L}{L_{\odot}} = \left(\frac{M}{M_{\odot}}\right)^{3.5}$$

where $L_{\odot}$ and $M_{\odot}$ are the luminosity and mass of the Sun. The H-R diagrams, shown in **Figure 10**, are used to compare very young stars to very old stars.

Structure of the Sun Although scientists cannot see inside the Sun, they have developed some theories about its interior. Much of what they know comes from studying its outer layers and its surface. The solar interior is composed of the core, the radiation layer, and the convection layer. The surface of the Sun is called the **photosphere**. This is the layer of the Sun that gives us light. The atmosphere above the photosphere is composed of the chromosphere and the corona. The Sun's structure is shown in **Figure 11**.

Solar Interior The innermost layer of the Sun is the core. This is where fusion occurs. The energy produced at the core may take millions of years to reach the photosphere where it is radiated into space.

The layer of the Sun just above the core is the radiation zone. In this layer, gases are completely ionized. Since no electrons remain on atoms to capture photons, this layer of the Sun is transparent to radiation. Energy formed by fusion travels easily through the radiation zone.

As you move farther outward from the Sun's core, the temperature drops and some electrons remain bound to their atoms. Here the gas becomes opaque to radiation and by the time you reach the outer edge of the radiation zone, all of the photons generated in the core have been absorbed. The energy from these photons is carried to the Sun's surface by convection through the next layer, the convection zone. Hotter gases from the bottom of this zone move upward toward the Sun's surface and cooler gases sink, setting up convection cells.

Energy for Life Plants use energy from the Sun and produce carbohydrates in a process called photosynthesis. When we burn fossil fuels, such as coal, we are using energy from the Sun that is stored in fossilized plant materials. Scientists also are trying to make direct use of solar energy by using solar cells. Research some applications of solar energy and share your results with your class.

Figure 11 The Sun's interior is divided into three parts: the core, the radiation zone, and the convection zone.

List three of the Sun's spheres or layers, starting with the surface and moving outward.

SECTION 2 Evolution of Stars 827

Identifying Misconceptions

The Sun is a Star Students often look at the Sun as the source of light and heat for Earth, but not as a star. The only reason the Sun is so bright compared to other stars is that it is so close to us. It is a star of average size, average temperature, and average brightness. Have students find the Sun on the H-R diagram. They will see that it (often referred to as Sol) is plotted along with many other main sequence stars.

Energy for Life Decayed organic materials deposited on seafloors were buried under layers of sediment. Then, the heat and pressure of these overlying sediments transformed them into the hydrocarbon fuels: oil, coal, and gas. Burning these fuels releases their stored energy. In burning they combine with oxygen from the atmosphere to form mostly carbon dioxide and water.

Caption Answer

Figure 11 photosphere, chromosphere, corona

LAB DEMONSTRATION

Purpose Students estimate the rate of movement of sunspots.

Materials clipboard, piece of cardboard, refracting telescope, small tripod, scissors, plain white paper

Preparation Cut a hole in the cardboard so it fits over the end of the telescope.

Procedure Set up the telescope with the eyepiece facing away from the Sun. Cover the finder scope. Project an image of the Sun onto the white paper on the clipboard. Trace any sunspots that appear on the lighted disk. Repeat the procedure daily for a week. Caution students to never look at the Sun through a telescope or directly with the unaided eye.

Expected Outcome Students will see sunspots moving across the Sun.

Assessment

What is the rate of sunspot movement over the week? **Possible answer:** Sunspots crossed about half the Sun in one week.

Make a Model

Structure of the Sun Have students make a model of the Sun's interior and surface using different colors of modeling clay. Encourage them to include some of the solar phenomena that occur on the photosphere, such as sunspots.

L2 ELL Visual-Spatial

✓ Reading Check

Answer darker, cooler spots on the Sun's photosphere

Quick Demo

Sunspots

Materials transparency of black line image

Estimated Time 5 minutes

Procedure Demonstrate why sunspots look dark on the Sun even though they are very hot. Have students look at an overhead projector screen. Ask them what color it is. Then turn on the projector. Ask them again what color is shown. Then place the black line transparency on the projector. Ask them what color the lines of the drawing are. **Possible answers:** Students will have said that the screen is white and bright white. Then they will say the lines are black. Explain to them that the lines look black because they are not as bright as the rest of the screen. Point out that the black lines are no blacker than the unlit portion of the screen. Sunspots look dark because they are not giving off as much light as the rest of the Sun.

L2 ELL Visual-Spatial

Post Reading

Discussion Have students discuss what they learned about the evolution of stars. For example, were they surprised to discover that some stars shrink and some stars expand as they die? What do they think about black holes? Does the information learned from the reading match up with what they have seen on television and in movies about black holes?

Figure 12 Sunspots, above, are often 2,000 K cooler than the surrounding granules, shown below.

Figure 13 This prominence of dense plasma appears suspended in the Sun's chromosphere as it loops back to the surface.

Photosphere The Sun's photosphere, or surface, is at the top of the convection zone and has a mottled appearance, called granulation. This is caused by rising hot material and sinking cooler material within the convection cells. Each granule shown in **Figure 12** is about 1,000 km across and is a direct result of convection cells in the convection zone.

Sunspots Some areas of the Sun appear darker than others. These darker areas of the Sun's photosphere, called **sunspots** are cooler than surrounding areas. Scientists can observe the movement of individual sunspots as they move with the Sun's rotation. They show that the Sun doesn't rotate as a solid body—it rotates faster at its equator than at its poles. Sunspots near the equator take about 25 days to go around the sun, but at about 60 degrees north or south latitude, they take about 31 days. **Figure 12** shows a closeup view of some sunspots.

✓ Reading Check

What is a sunspot?

Sunspots aren't permanent features of the Sun. They appear and disappear over periods of days, weeks, or months. The number of sunspots changes in a fairly regular pattern called the sunspot, or solar activity, cycle. Periods of sunspot maximum occur about every 11 years, with periods of sunspot minimum occurring in between. At a sunspot minimum, sunspots appear at high latitudes. As the cycle progresses, they appear closer to the Sun's equator. By the next minimum, they again cluster at high latitudes.

Prominences and Flares Intense magnetic fields associated with sunspots can cause huge arching columns of gas called prominences to erupt, as shown in **Figure 13**. Convection in the convection zone causes magnetized gases to flow upward toward the photosphere. Sometimes the magnetic field strength is great enough that magnetic field lines shoot out from the surface near a pair of sunspots and cause a prominence of solar material to loop from one spot to the other. Some prominences blast material from the sun into space at speeds ranging from 600 km/s to more than 1,000 km/s.

Gases near a sunspot sometimes brighten suddenly, shooting gas outward at high speed in what are called solar flares. Temperatures within these flares can reach 100 million K. Particles produced in a flare possess so much energy that the Sun's magnetic field cannot hold them as it can hold prominences and they blast into space.

Differentiated Instruction

Hearing Impaired Help your hearing-impaired students better understand the structure of the Sun. As you present the different layers of the Sun and what happens to energy at each layer, draw a cross-section of the Sun's interior on the chalkboard. Use a different color of chalk for each layer and include several of the photosphere's surface phenomena, such as sunspots and flares. L2 ELL Visual-Spatial

Visual Learning

Figure 12 Help students understand the information presented in **Figure 12**. The granulation shown on the surface of the Sun is caused by rising and falling gases in the convection layer. Rising columns of gas are hotter and brighter and sinking gases are cooler and darker. The sunspots also are darker, cooler regions on the photosphere. L2 ELL Visual-Spatial

DAILY INTERVENTION

Check for Understanding

Visual-Spatial Show students images of three different stars. Show Betelgeuse, which is cooler and hundreds of times larger than the Sun; Sirius A, which is a little hotter and twice as large as the Sun; and Sirius B, which is much hotter, but much smaller than the Sun. Ask them to classify the three stars. Possible answer: Betelgeuse is a supergiant, Sirius A is a main sequence star, and Sirius B is a white dwarf. L2 ELL

Reteach

Sunspots Ask students to draw an image of sunspots on the Sun and to explain why they are visible on the Sun's photosphere. Possible answer: Students should draw an image of the Sun with dark spots visible on the Sun's photosphere. Students may draw dark spots surrounded by an area that is not quite as dark. They are darker than surrounding areas of the Sun because they are about 1,000 degrees cooler. L1 ELL

Visual-Spatial

Assessment

Oral The most common type of star in the universe is the red dwarf, a main sequence star. Ask students why many of the bright stars we can see in the sky are giants. Possible answer: Most easily visible stars are giants because they have large surface areas that emit large amounts of light and can be seen from great distances. Use PASC, p. 89 L2

Figure 14 CMEs like this one can hurl a million tons of matter into space each second. They can damage satellites and endanger astronauts.

CMEs Sometimes large bubbles of ionized gas are emitted from the Sun. These are known as CMEs (coronal mass ejections). During sunspot minimums there is usually one CME per week, but during a sunspot maximum, there are two to three per day. When a CME is released in the direction of Earth, it appears as a halo around the Sun, as shown in **Figure 14**. As it passes Earth, the planet is exposed to a sudden shock wave of increased solar wind. Earth's atmosphere protects us, but occurrences of auroras increase. When scientists note a CME, they post an alert to watch for auroras at lower latitudes than normal.

Auroras take place when high-energy particles in CMEs and the solar wind are carried past Earth's magnetic field. This generates large electric currents that flow toward Earth's poles. These electric currents ionize gases in Earth's atmosphere. When these ions recombine with electrons and drop to a lower energy level, they produce light. This light is called the aurora borealis, or northern lights, when it occurs in the northern hemisphere. In the southern hemisphere, it is called the aurora australis. CMEs present little danger to life on Earth, but some of the highly charged solar wind material disrupts Earth's magnetosphere and interferes with orbiting satellites and radio signals.

section 2 review

Summary

How do stars form?

- Stars form from a large cloud of gas, ice, and dust. Once the temperature inside the nebula reaches 10 million K, fusion begins.
- The H-R diagram plots temperature v. absolute magnitude of stars.

How do stars change?

- Once fusion begins, a star develops stellar equilibrium and becomes a main sequence star.
- When the hydrogen fuel is depleted, a star loses stellar equilibrium and evolves into a giant, or a supergiant.

The Sun—A Main Sequence Star

- The Sun's energy is produced by fusion.
- Sunspots are dark, cooler regions on the Sun's photosphere.
- Other solar features that can affect Earth are prominences, flares, and CMEs.

Self Check

1. **Explain** how stars form from nebulae.
2. **Describe** the different evolution stages of stars as shown on the H-R diagram.
3. **Describe** the structure of the Sun.
4. **Explain** the difference between Type I and Type II supernovas.
5. **Think Critically** What happens to stellar equilibrium to make a main sequence star evolve into a giant star?

Applying Math

6. **Use Percentages** Eighty percent of all stars are red dwarfs. Out of a random sample of 2,000 stars in the galaxy, about how many will plot on the H-R diagram as a red dwarf?
7. **Use Numbers** If the Sun will remain a main sequence star for a total of 10 billion years and Proxima Centauri will remain one for 16 trillion years, how many times longer will Proxima Centauri be a main sequence star?

section 2 review

1. Nebulae fragment, condense and flatten. Matter concentrates in the center where temperature increases. At about 10,000,000°C, hydrogen fuses into helium, producing heat and light.
2. Once a star achieves stellar equilibrium, it is a main sequence star. Stars can change into giants or supergiants.

Giants evolve into white dwarfs. Supergiants will undergo supernova explosions and become neutron stars or black holes.

3. The Sun's interior has three layers; the core, the radiation layer, and the convection layer. The photosphere is the Sun's surface. Above the surface is the

atmosphere containing the chromosphere and the corona.

4. Type I supernovas form from hydrogen-poor, low-mass stars that have pulled in material from a nearby red giant star; they are destroyed completely. Type II supernovas form from hydrogen-rich, high-mass stars; they leave cores that

form neutron stars or black holes.

5. Stellar equilibrium is lost when hydrogen is exhausted. The core contracts, temperatures rise, and the outer layers of the star expand.
6. 1,600 stars
7. 1,600 times longer

MA.A.3.4.1

Real-World Problem

Purpose Students will compare and contrast H-R diagrams and determine the relative ages of four star clusters.

Process Skills compare and contrast, infer, interpret scientific illustrations, use graphs

Time Required 30 minutes

Procedure

Teaching Strategies Make transparencies of different star clusters. Select clusters having different ages. For example, the h and chi Persei double cluster (NGC 869 and 864), the Hyades, NGC 188 (in Cepheus), and 47 Tucanae (NGC 104). These H-R diagrams are available in many astronomy books and Internet sites.

Troubleshooting Remind students of the locations of giants, white dwarfs, and main sequence stars on the H-R diagram.

Conclude and Apply

1. Different types of stars are shown on H-R diagrams of different star clusters.
2. The youngest star cluster will not have giants or white dwarfs. High-mass stars will have evolved off the main sequence with some having evolved to white dwarfs in the oldest star cluster.
3. The number of low-mass stars on the main sequence and what has happened to high-mass stars help determine the relative ages of the star clusters.
4. Answers will vary.
5. Check how many high-mass stars have evolved off the main sequence.

LAB

Star Cluster Age

Stars are plotted on the H-R diagram based on their temperature and brightness. You can determine the age of a cluster of stars by studying the H-R diagram of the stars within the cluster. Massive main sequence stars, located at the upper left of the diagram, evolve faster than stars farther down the main sequence. Stars in the lower right of the diagram evolve more slowly. How could you use this idea to help determine the relative ages of star clusters from their H-R diagrams?

the relative ages of the other two star clusters. *HINT: The oldest cluster will have some that have evolved to white dwarfs.*

Real-World Problem

How can the relative age of star clusters be determined from H-R diagrams of each cluster?

Goals

- **Compare and contrast** H-R diagrams of several star clusters.
- **Determine** the relative ages of four star clusters.

Materials

four H-R diagrams of star clusters

Procedure

1. Study the four H-R diagrams your teacher gives you.
2. Note which types of stars remain on the main sequence and which stars have evolved off the main sequence.
3. Based on the evolution of the stars within each star cluster, decide which cluster is youngest and which is oldest. Also decide

Conclude and Apply

1. **Compare and contrast** H-R diagrams of four star clusters.
2. **Determine** which star cluster was youngest and which was oldest.
3. **Explain** how you determined the ages of these two star clusters.
4. **Determine** the relative ages of the remaining two star clusters.
5. **Explain** how you determined the ages of these two star clusters.

Communicating Your Data

Explain to your friends how the relative ages of star clusters can be found by studying H-R diagrams.

Assessment

Process Show students a transparency of the H-R diagram of the Pleiades star cluster. Ask them to determine its relative age compared to the other star clusters they evaluated in this lab. **Possible answer:** The Pleiades is older than the h and chi Persei double cluster, but younger than the Hyades star cluster. Use PASC, p. 99. **L2 ELL Visual-Spatial**

Communicating Your Data

Have students discuss with one another any differences they used to help determine the relative ages of the four star clusters.

Galaxies and the Milky Way

SC.E.2.4.6 The student knows the various ways in which scientists collect and generate data about our universe (e.g., X-ray telescopes, computer simulations of gravitational systems, nuclear reactions, space probes, and supercollider simulations).

Reading Guide

What You'll Learn

- **Explain** that the same natural laws that apply in the Milky Way Galaxy also apply in other galaxies.
- **Compare** the three main types of galaxies.
- **Describe** the Milky Way galaxy and the Sun's position in it.

Why It's Important

The Milky Way galaxy is your galaxy and you can see part of it stretching across the evening sky.

- **Review Vocabulary**
ellipse: oblong, closed curve

New Vocabulary

- galaxy
- Milky Way
- Local Group

Galaxies

One reason to study astronomy is to learn about your place in the universe. Long ago, people thought Earth was at the center of the universe. You know this isn't true, but do you know where you are in the universe?

You are on Earth, and Earth orbits the Sun. But the Sun orbits something else and it interacts with other objects in the universe. The Sun is one star among billions of stars in a galaxy. A **galaxy** is a large group of stars, gas, and dust held together by gravity, shown in **Figure 15**. Our galaxy, called the **Milky Way**, contains 400 billion stars, by most recent estimates, including the Sun. Countless other galaxies exist throughout the universe—an estimated 40 billion galaxies can be seen. Each of these galaxies contains the same elements, forces, and types of energy as our galaxy. There are three major types of galaxies: spiral, elliptical, and irregular.

Spiral Galaxies Take another look at **Figure 15**. Notice that spiral galaxies have spiral arms that wind outward from the galaxy's center. These spiral arms are made up of bright stars, dust, and gas. Our neighbor, the Andromeda galaxy, is visible to the unaided eye as a fuzzy patch in the constellation Andromeda. It is a normal spiral galaxy with its arms starting close to center. Barred spirals are another type of galaxy that have spiral arms extending from a large central bar of stars, dust, and gas that passes through the center, or hub, of the galaxy. Astronomers are not certain whether the Milky Way is normal or barred spiral.

Figure 15 Spiral galaxy 4414.

Galaxies often are millions of light-years apart.

Explain what is meant by a million light-years.

Inquiry Lab

Counting Stars

Question What volume of salt grains represents the number of stars in the Milky Way galaxy?

Possible Materials salt, sand, pipettes, 10-mL graduated cylinder, colored paper, calculator

Estimated Time 20 minutes

Teaching Strategies

- Warn students never to eat anything during science class.
- Students can measure 0.1 mL of salt grains and pour them onto colored paper. They can spread the grains and estimate their number by counting by fives. For easier counting, the grains can be divided into sections.
- There are 5,000 salt grains in 1 mL of salt. Students can divide the number of Milky Way stars (400 billion) by 5,000 to calculate the volume of salt grains needed to represent the number of stars in the galaxy.

80,000,000 mL or 80,000 L

- Encourage students to visualize the volume of salt grains by calculating the number of 38-L (10-gallon) aquariums it would fill. **approximately 2,105 aquariums**

For additional inquiry activities, see *Science Inquiry Lab Manual*.

Figure 16 In ultraviolet light, this elliptical galaxy reveals a core of thousands of old, helium-burning stars.

Identify the most common type of galaxies in the universe.

Elliptical Galaxies Astronomers once thought that spiral galaxies were the most common galaxies because they are relatively large and easy to see. But as observations of the universe became more detailed, it became clear that most galaxies are elliptical galaxies, and most of these are dwarf galaxies. They are just too small and dim to be easily seen.

These galaxies are shaped like large, three-dimensional ellipses. Many are football-shaped, but others are spherical as shown in **Figure 16**. These giant elliptical galaxies can be over 9 million light-years across and contain trillions of stars. However, most dwarf ellipticals are only about 3,000 light-years across and contain fewer than a million stars.

Irregular Galaxies Most galaxies that aren't elliptical or spiral are considered irregular galaxies. They take many different shapes and contain 100 million to 10 billion stars, making them larger than dwarf ellipticals but smaller than spirals. Irregular galaxies are less common than spirals or ellipticals.

Two irregular galaxies called the Clouds of Magellan orbit the Milky Way. One of these, known as the Large Magellanic Cloud, is shown in **Figure 17**. Several other dwarf galaxies also are affected by the Milky Way's gravity. One of these, the elliptical Sagittarius dwarf, is being absorbed by the Milky Way. This dwarf galaxy lies about 60,000 light-years from the center of the Milky Way on the opposite side of the galaxy from us and 20,000 light-years below the galactic plane.

The Local Group Just as stars are grouped together within galaxies, galaxies are grouped into clusters. Clusters of galaxies are even grouped into superclusters. Our Milky Way galaxy belongs to a cluster called the **Local Group**. It is a relatively small cluster containing about 45 galaxies of various types and sizes, most of which are dwarf elliptical galaxies. The largest galaxy in the Local Group is the Andromeda galaxy, a spiral galaxy a little larger than ours that lies about 2.6 million light-years away. If the Andromeda galaxy and the Milky Way galaxy continue to travel through space as they are, they may collide in the distant future.

Figure 17 The irregular structure of the Large Magellanic Cloud might have been produced by interactions with the Milky Way galaxy.

Visual Learning

Figure 17 Explain to students that before today's powerful telescopes were available, these objects were thought to be nebulae or "clouds." Today we know they are galaxies in the local group. Because of their locations in the southern skies, these galaxies are not visible from the United States. They were named for explorer Ferdinand Magellan, who observed them on his voyage. L2 ELL IS **Visual-Spatial**

Differentiated Instruction

Learning Disabled Have each of your learning-disabled students work with another student. Encourage the teams of students to make flash cards of each of the major types of galaxies. Provide student teams time in class to quiz each other on galaxy types. Suggest that students identify the type and one key property that led to its classification.

L1 ELL IS **Visual-Spatial**

How do galaxies form?

Astronomers aren't sure how galaxies originally formed. It is thought that fluctuations in density of primordial matter in the universe began to form blobs of gas that would eventually form into galaxies. These blobs might have had masses equivalent to the mass of the dwarf galaxies. In fact, one idea is that the dwarf galaxies may be remnants of these earlier blobs of matter.

Most astronomers now believe that the galaxies we see closer to us grew by absorbing or merging with other smaller objects. One bit of evidence that supports this idea is that more distant galaxies tend to be much smaller than those closer to the Milky Way. It makes sense to conclude that these smaller galaxies that existed long ago merged to make the larger, more organized galaxies of the universe today. Also, we have evidence that galaxies do collide.

Colliding Galaxies In some galaxy clusters, the galaxies are concentrated very close together. In the Virgo Cluster, for example, thousands of galaxies orbit within 10 million light-years of each other. Do these galaxies collide? If so, what happens to them and to the stars within them? It seems that little happens to the individual stars within the galaxies. There is so much open space between the stars that the individual stars of the two galaxies just move past each other.

Reading Check What happens to individual stars in colliding galaxies?

However, galaxy collisions have a strong effect on the overall structure and shape of the colliding galaxies. They may lose all of their spiral shape, if they had any.

It is thought that the two galaxies shown in **Figure 18** will eventually collide. The smaller galaxy on the right does not seem to have enough energy to escape the larger one to the left. When galaxies interact by passing close to each other or by colliding, there is a burst of star formation in each. Their interstellar gas and dust clouds are shocked and squeezed, leading to star formation. This can be detected by the blue light emitted by young, hot stars.

Figure 18 In about a billion years, these two galaxies will merge. Much of their spiral structures probably will be lost.

Use an Analogy

Merging Galaxies Explain to students that water droplets running down a windowpane and merging into larger droplets that run even faster is analogous to the way large galaxies form by absorbing and merging with smaller galaxies. **L2**

ELL **Visual-Spatial**

Reading Strategy

Close Reading Read the text on The Local Group to students and show them how to take apart the text in phrases to understand the content. Then, make notes on the board as you read the text titled We live in a Supercluster. in a Cluster—named Local Group in a Galaxy—named Milky Way in a star system—named solar system on a planet—named Earth

Discussion

Sagittarius Dwarf Galaxy Astronomers have said that small galaxies like the Sagittarius dwarf elliptical galaxy are the building blocks of larger galaxies like the Milky Way. Have students research this galaxy and the infrared survey used to learn about it, called the Two-Micron All Sky Survey (2MASS). Have them discuss what (2MASS) means for the future of these two galaxies and other nearby galaxies, such as the Large and Small Magellanic Clouds. **Possible answer:** The stars, gas, and dust and any other objects in the smaller galaxies near the Milky Way will be absorbed and the Milky Way will continue to grow. **L2**

Reading Check

Answer Probably nothing; because stars are so far apart, they will move past each other.

Quick Demo

It's a Spiral

Materials pinwheel

Estimated Time 5 minutes

Procedure Hold a pinwheel toy in front of the class. Demonstrate how the blades of the pinwheel seem to spiral out from its center. Now gently blow on the pinwheel to make it turn. Relate this shape and movement to the shape of the Milky Way Galaxy and its slow turning movement. **L2** **ELL** **IS**

Answer spiral or barred spiral

Visual Learning

Figure 20 Help students understand the information presented in Table 1. The illustration shows the Milky Way as if you were looking down on it. It is a spiral galaxy with a radius of 50,000 light-years. The Sun is about halfway out at a distance of 26,000 light-years from the center. Note the bar shape to the nucleus; recent indications are that the Milky Way is a barred spiral. **L2** **ELL** **IS** **Visual-Spatial**

Caption Answer

Figure 20 a cubic volume of space that is one light-year in length, width, and depth.

Post Reading

Discussion Have students look back into the text of this section and illustrate the Milky Way. Ask them to label the light-year distances of the Sun to the center, the length of the spiral arms, and the distance through the central bulge. In small groups, have them present their drawings as prompts for discussion.

Science Online

Topic: The Milky Way Galaxy

Visit fl.gpscience.com for Web links to information about the Milky Way galaxy.

Activity Draw a model of the Milky Way galaxy showing its possible barred structure. Include the approximate location of the Sun and information about the Sagittarius dwarf galaxy.

Figure 19 The swirls of red seen in this model are stars in the remnants of the Sagittarius dwarf elliptical galaxy.

Figure 20 Star density is greatest near the center of the Milky Way, with over 1,400 stars in every cubic light-year of space. The Sun is located about halfway out on the Orion arm of the Milky Way galaxy.

Explain what is meant by a cubic light-year.

834 CHAPTER 26

The Milky Way

Recall that the Milky Way galaxy contains about 400 billion stars, including our Sun. The Sun makes one complete orbit around the center of the Milky Way in about 225 million years, traveling at a speed of 220 km/s. This means that since it formed, the Sun has made a little over 22 orbits of the Milky Way.

The Milky Way is usually classified as a normal spiral galaxy. However, recent evidence suggests that it might be a barred spiral. It is difficult to know for sure because astronomers can never see our galaxy from the outside. You can't see the normal spiral or barred shape of the Milky Way because the Sun and Earth are located within one of its spiral arms. However, you can see the Milky Way stretching across the sky as a faint band of light. All of the stars you can see belong to the Milky Way galaxy.

Reading Check What type of galaxy is the Milky Way?

Evidence indicates that the Milky Way, like many galaxies, grows by absorbing other galaxies. It has been gobbling up the Sagittarius dwarf elliptical galaxy for 2 billion years. If we could see infrared light, we could see stars and other material from this galaxy becoming part of our section of the Milky Way, as shown in Figure 19. Eventually, the Milky Way probably will absorb both Clouds of Magellan and several other dwarf galaxies.

Structure of the Milky Way The Milky Way galaxy, shown in Figure 20, measures about 100,000 light-years from one side to the other. The Sun lies about 26,000 light-years from the galactic center on the edge of one of the spiral arms. The Milky Way's disk is about 1,000 light-years thick—it would take 1,000 years to travel from top to bottom even at the speed of light. The central bulge of the Milky Way is about 10,000 light-years in diameter.

Cultural Diversity

The Milky Way The fluid form of the Milky Way is reflected in the interpretations of many different cultures. Akkadians called it the River of the Snake. In Judea, Armenia, and Syria, it was called a long bandage. In China and Japan, it was called the Celestial River. Polynesians called it the Long, Blue, Cloud-Eating Shark. In India, it was known as the Bed of the Ganges.

Curriculum Connection

Math A parsec (pc) is the distance to a star that has a parallax angle of one second of arc. Each parsec equals 3.26 light-years. Ask students to calculate the radius of the Milky Way and the distance from its center to the Sun in parsecs. **Possible answer:** Students should use the equation: $d_{pc} = d_{ly} / 3.26$. The Sun is 26,000 ly from the center; $26,000 / 3.26 = 8000$ pc **L3**

IS Logical-Mathematics

Spiral Arms The arms of a spiral galaxy look like pinwheels that begin near the galactic center and extend outward through the disk of the galaxy. These spiral arms contain both young stars and prestellar material, such as glowing nebulae. Young open star clusters are present too. This is the part of a spiral galaxy where stars are forming. Astronomers do not yet fully understand what causes the spiral structure to form. They speculate that it might be caused by instabilities in the gas near the galactic bulge or gravitational effects of other galaxies that are or were nearby, or might be just an extension of the shape of the galactic bulge, itself. They just don't know.

Galaxy Center What strange objects lurk in the very dense population of stars at a galaxy's core? Recent theories suggest that extremely massive black holes might exist at the cores of galaxies. The problem is that this part of a galaxy is hidden from view by material that exists in between the densely packed stars. The total energy emitted from an object called Sgr A* (saj-ay-star), located in the nucleus of the Milky Way, is equivalent to the energy that would be emitted by a million suns. The leading theory about this object, shown in **Figure 21**, is that it is a supermassive black hole, containing the mass of 3 million suns.

Figure 21 This bright radio source captured by the VLA is indirect evidence of a black hole at the center of our galaxy.

3 Assess

DAILY INTERVENTION

Check for Understanding

Visual-Spatial Have students draw an illustration of the Milky Way galaxy as a spiral or a barred spiral galaxy. Ask students to position where Earth and the Sun are located. **Possible answer:** Students should indicate that the Sun and everything on Earth would be located about halfway out of the center of the Milky Way. **L1 P**

Reteach

Milky Way's Center If there are about 1,400 stars in every cubic light-year at the galaxy's center, how many more stars are there than in the area of the Milky Way where the Sun is located? **Possible answer:** Since the closest star to the Sun is over 4 light years away, the center of the Milky Way contains about 1,400 more stars per cubic light year than is found in the area near the Sun.

L2 LS Logical-Mathematical

Assessment

Oral The most common type of galaxy in the universe is the dwarf elliptical. Why did astronomers once think that spiral galaxies were the most common? **Spiral galaxies are much larger and brighter than dwarf ellipticals, therefore it was easier to see them than the smaller dwarf elliptical galaxies.** Use **Performance Assessment in the Science Classroom**, p. 93. **L2**

section 3 review

Summary

Galaxies

- A galaxy is a large group of stars, gas, and dust held together by gravity.
- The three main types of galaxies are elliptical, irregular, and spiral.

How do galaxies form?

- Astronomers believe that galaxies form by absorbing or merging with smaller objects.
- Young, hot stars form when galaxies collide, but individual stars within each galaxy are not affected much.

The Milky Way Galaxy

- The Milky Way galaxy contains about 400 billion stars and has a spiral shape.
- The Milky Way galaxy is about 100,000 light-years across and the Sun lies about 26,000 light-years from its center.
- Supermassive black holes are thought to exist in the centers of galaxies.

Self Check

1. **Compare and contrast** the Milky Way galaxy to other galaxies in the universe.
2. **Describe** the three main types of galaxies.
3. **Draw** the overall structure of the Milky Way galaxy and indicate where the Sun is located.
4. **Describe** the most common type of galaxy.
5. **Think Critically** How might the Sun be affected if the Andromeda galaxy and the Milky Way galaxy collide.

Applying Math

6. **Use Numbers** Assume there are 400 billion stars in the Milky Way galaxy, plus or minus 200 billion. Based on this estimate, what is the range of the number of stars that might exist in the Milky Way?
7. **Use Percentages** A dwarf elliptical galaxy has fewer than 1 million stars and a small irregular galaxy contains 100 million stars. What percent of the number of stars found in a small irregular galaxy are found in a dwarf elliptical galaxy?

section 3 review

1. All galaxies are large families of stars, gas, and dust. The Milky Way is a spiral galaxy; larger than dwarf ellipticals, but not as large as giant elliptical galaxies.
2. Elliptical galaxies have a spherical or elliptical shape with no structure. Spiral galaxies have a central hub with arms spiraling out from it. Irregular galaxies have no structure and can be any shape.
3. Student drawings should show a spiral pattern, with a central hub and the Sun about halfway out from the center.
4. Dwarf ellipticals are small, and resemble round to elliptically shaped balls.
5. Little will happen to individual stars like the Sun; they will just move past each other.
6. 200 billion to 600 billion stars
7. less than 1 percent

Cosmology

SC.E.2.4.2 The student identifies the arrangement of bodies found within and outside our galaxy.
SC.E.2.4.5 The student knows various scientific theories on how the universe was formed.
SC.E.2.4.7 The student knows that mathematical models and computer simulations are used in studying evidence from many sources to form a scientific account of the universe.

Tie to Prior Knowledge

The Big Bang Ask students how the universe began. Some will reply that it started with a big bang. Ask them what this big bang was. *One theory explains that the universe was smaller than it is today. A large explosion caused the universe to rapidly expand.* L2

SQ3R This five-step strategy helps promote active reading. Have students first **Survey** the section, focusing on headings. Students should then develop **Questions** about key concepts. Next, students should **Read** the section, keeping their questions in mind. Last, have students **Recite** the vocabulary words and **Review** their definitions.

Reading Guide

What You'll Learn

- **Describe** the most accepted theory about the origin of the universe.
- **Define** dark matter.
- **Explain** how dark energy may cause the universe to expand forever.

Why It's Important

Conditions that existed when the universe began led to the formation of galaxies like the Milky Way.

Review Vocabulary

universe: the space that contains all known matter and energy

New Vocabulary

- cosmology
- big bang theory
- dark matter
- dark energy

How did it begin?

The study of the universe—how it began, how it evolves, and what it is made of—is known as **cosmology**. Several models of the origin and evolution of the universe have been proposed.

One model, proposed in 1948, is called the steady state theory. In this theory, the universe has always existed and it always will. As the universe expands, new matter is created. The density of the universe remains the same or in steady state.

A second idea is called the oscillating model. In this model, the universe expanded rapidly, then slowed, and eventually contracted. This oscillating process continues back and forth through time. Some scientists currently believe that enough matter exists to cause the universe to eventually contract.

Figure 22 This map produced by the WMAP team has been called a “baby picture” of the universe. It is oval because it is a projection, just as maps of Earth can be projected as ovals. *Infer why this map is called a “baby picture” of the universe.*

The Big Bang Theory

The most accepted theory of how the universe formed is the **big bang theory**. It states that the universe started with a big bang, or explosion, and has been expanding ever since. The big bang is not like an explosion of matter into empty space; it is the rapid expansion of space itself.

When did it begin? A NASA-related mission, called the Wilkinson Microwave Anisotropy Probe (WMAP), produced a map of the oldest light in the universe. Based on the map, shown in **Figure 22**, and other data, the WMAP team proposed a more specific age of the universe. Their findings indicate that the universe began about 13.7 billion years ago with a big bang. The team believes its data are correct within a one percent margin of error. They measured temperature variations over the entire universe found in the cosmic microwave background radiation. This radiation is thought to have been produced about 400,000 years after the big bang when temperatures became low enough for atoms to form. Bright areas of the map are thought to indicate places that collapsed, forming the galaxies that we see today.

Reading Check When did the universe begin?

Expansion of the Universe

The motion of stars within the Milky Way can be detected by using the Doppler effect. For example, sound waves from a moving source are compressed as the object approaches and stretched as it recedes. Doppler shifts occur in light as well as sound. If a star approaches Earth, its wavelengths of light are compressed, causing a blue shift. If a star moves away, its wavelengths are stretched, causing a red shift. Using the Doppler shift, scientists found that some galaxies in the Local Group are moving toward, some are moving away, and others are moving with the Milky Way. A red shift is also seen in the light from distant galaxies, but this is explained differently.

Figure 23 The observer on the right experiences a blue shift as wavelengths of light emitted by an approaching object are compressed. The observer on the left experiences a red shift as wavelengths are stretched.

SECTION 4 Cosmology 837

Reading Strategy

Clarify Text Have a student read the text about Expansion of the Universe while others demonstrate the Doppler effect shown in **Figure 23**. Have them continue this modeling process as other students take turns reading the subsequent topics. Conclude with the concept of acceleration of expansion of the universe.

Visual Learning

Figure 22 Help students understand that the oval shape of this photo is a projection designed to show the whole sky. This is similar to the way Earth globes are projected as ovals. Also, the image was made using microwaves that were translated into visual wavelengths. Red shows warmer areas and blue shows cooler areas, the reverse of star colors. **L2 ELL AS Visual-Spatial**

INTEGRATE Language Arts

Science as Literature Many famous scientists have written about science for the general public. Among them are physicists Albert Einstein and George Gamow. More recently, physicist Stephen Hawking wrote "A Brief History of Time," which describes current theories of how the universe began. Research the work of Steven Hawking and his contributions to cosmology and write a brief biography.

2 Teach

Caption Answer

Figure 22 It is a picture of the earliest radiation produced in the universe.

Reading Check

Answer 13.7 billion years ago

INTEGRATE Language Arts

Science as Literature Many writers of science fiction were originally scientists. For example, Isaac Asimov was a professor of biochemistry before turning to writing full time. Also, Arthur C. Clarke, best known for the book and film "2001—A Space Odyssey", was the scientist who first proposed placing a satellite in geostationary orbit for weather and communications. In fact, the geostationary orbit at 42,000 km was named for him by the International Astronomical Union. Other science fiction writers combine careers, such as Jerry Pournelle, who writes both science fiction and a nonfiction column in computer science.

Fun Fact

The rotation rate of the Sun can be determined from the Doppler effect. Light from the left side of the Sun shows a slight blue shift and light from the right side shows a slight red shift. The amount of the shift is related to the rate of rotation for the Sun.

Quick Demo

Doppler Effect

Materials a ball that whistles when thrown.

Estimated Time 5 minutes

Procedure Attach a strong piece of rope to the ball and carefully twirl the ball around your head. Stand about 5 m away from students. As the ball twirls around, students will hear a higher pitch as the ball approaches them and a lower pitch as the ball moves away. Relate the changing wavelengths of sound waves to the changing wavelengths of light caused by a star coming toward or going away from Earth.

L2 ELL Visual-Spatial

Activity

Expansion of the Universe Have students cut stars out of a piece of cotton and attach them at various positions on a 5-cm wide strip of spandex. Tell them to hold the ends of the spandex strip in both hands and slowly pull on both ends. Students will observe the distance between the stars (galaxy clusters) increases as space expands. **L1 ELL** Visual-Spatial

Discussion

Dark Matter and Dark Energy Have students research the existence of dark matter and dark energy. Have them discuss the presence of both dark matter and dark energy. Possible answer: The rate at which the Sun orbits the center of the Milky Way is incorrect if only the visible mass of the Milky Way is taken into account. The expansion of the universe appears to be greater now than in the past. There must be an energy source for this accelerated expansion. **L3**

Reading Check

Answer regular matter

Caption Answer

Figure 6 voids

Figure 24 This *Hubble* view looks deep into space and time when the universe was more chaotic and oddly shaped galaxies were common. Dark matter might have influenced galaxies to take the classic spiral and elliptical forms we see today.

Hubble Red Shift The Doppler shift does not explain the shift in wavelength of light coming from distant galaxies. This shift is known as the *Hubble* red shift. It is caused by the stretching of space itself as the universe expands. Light waves traveling through space lengthen as space expands. The fact that this red shift is seen in the light from all galaxies outside the Local Group indicates that the entire universe is expanding.

What is the universe made of?

The way in which galaxies like the Milky Way rotate and move should depend on the amounts of mass they contain. The problem is that if only the visible or otherwise detectable mass (called regular matter) is counted, the Milky Way and other galaxies shouldn't be rotating, moving, and interacting with other galaxies the way they are. It appears that regular matter makes up only a very small amount of the known universe. Much of the mass that must be present cannot be seen. However, its effect on other galaxies can be seen, shown in **Figure 24**. This unseen and little-understood matter that affects galaxies has been named **dark matter**.

Reading Check

Which type of matter is considered to make up the least amount of the universe?

Differentiated Instruction

Hearing Impaired Help your hearing impaired students achieve success in note taking by setting up paired partners. Pair each of your hearing impaired students with another student. During the lesson, they should work together to write down all notes. The hearing impaired student should concentrate on information on the board and the other student on information presented by voice. **L2** Linguistic

Teacher FYI

Standard Candles A standard candle, like a Type I supernova, is always considered to have the same absolute brightness. If a standard candle is recognized in another galaxy, its apparent brightness is compared to its absolute brightness. This comparison can be used to determine the distance to the galaxy in which the supernova exists.

Dark Matter Although scientists are uncertain about what dark matter is, the concept helps them explain how the universe may have formed. Temperature variations, as shown on the WMAP map, could have led to density fluctuations in the early universe. As the universe expanded, gravity from dark matter pulled matter together in regions with higher density. Galaxies could have formed in the denser regions and voids could have formed elsewhere. This structure is seen when sections of the universe are mapped, as shown in **Figure 25**.

Figure 25 These maps of sections of the universe show areas densely populated with galaxies and other areas almost empty.

Identify What are the almost-empty areas called?

Dark Energy Data indicate that the expansion of the universe is accelerating. Explaining this acceleration is difficult. One hypothesis is that a form of energy, called **dark energy**, might be causing the acceleration. When matter was closer together in the early universe, gravity could easily overcome expansion caused by dark energy. Now, with matter farther apart, gravity is insufficient to overcome it and expansion accelerates. This does not mean, however, that dark energy is related to dark matter.

section 4 review

Summary

How did it begin?

- Cosmology is the study of how the universe began and evolves.
- The big bang theory is the most accepted theory about the beginning of the universe.
- The universe is estimated to be 13.7 billion years old.

Expansion of the Universe

- The Doppler effect indicates whether stars are coming toward Earth or moving away.
- The Hubble red shift is caused by the expansion of space and the entire universe.

What is the universe made of?

- The universe might contain dark matter and dark energy.

Self Check

1. **Define** cosmology.
2. **Describe** the big bang theory.
3. **Explain** how the expansion of space could cause a red shift in the light from distant galaxies.
4. **Describe** the Doppler effect.
5. **Think Critically** How could the presence of some repulsing force cause the universe to expand forever?

Applying Math

6. **Use Percentages** The currently accepted age of the universe is 13.7 billion years plus or minus one percent. How much time does this one percent represent?
7. **Use Percentages** What percent of the universe's age is the first 400,000 years?

Post Reading

Summarize Have students work in pairs to summarize the effects of the opposing forces of gravity and expansion of space on matter. Have them consider colliding galaxies and the star sequences of giant and supergiant stars. Encourage them to look back in the text to check for accuracy.

3 Assess

DAILY INTERVENTION

Check for Understanding

Linguistic Have students write a paragraph about why astronomers think the universe had a beginning. *Galaxy clusters are expanding away from all other galaxy clusters. This implies that they were all closer together in the past when all matter was together.* L2 P

Reteach

Expansion of the Universe What is true of light coming from distant galaxies? *Light from galaxies outside of the Local Group has been lengthened by the expansion of space.* L2

Assessment

Content Explain how the Doppler effect can tell scientists whether a star is approaching or moving away from Earth. *Light that is moving away is shifted toward the red end of the spectrum; if it is moving toward us, light is compressed and is shifted toward the blue end of the spectrum.* L2

section 4 review

1. the study of how the universe began, how it continues to evolve, and what it is made of
2. The universe started with a big bang and has been expanding ever since.
3. As space expands, it causes the light waves to expand as well, thus lengthening the wavelengths or shifting them toward the red end of the spectrum.
4. The Doppler effect is caused by the movement of an object. If it is moving away, its light is lengthened in wavelength; if it is moving toward you, its light is shortened in wavelength.
5. As matter expands more and more, the expansion force would overcome any attractive force that exists between the matter.
6. 137 million years
7. 0.003 percent

MA.A.3.4.1

 Video Lab available for this Lab.

Real-World Problem

Purpose Students will model the stretching of the wavelength of light caused by expansion of the universe.

Process Skills Make a model, analyze results, collect data, draw and label, draw conclusions, infer, interpret data, make and use tables, observe, organize data, recognize cause and effect.

Time Required 35 minutes

Possible Materials round balloon, permanent marker, medium-sized binder clip

Safety Precautions

- Caution students not to over inflate the balloon, it could burst.
- Caution students to handle the binder clip carefully; it can slip out of their hands.

Make a Model

Possible Procedures Slightly inflate the balloon and clip it shut. Mark the location of the galaxy clusters. Use a metric ruler to measure the distances between the galaxy clusters. Record these measurements. Draw a wavy line from the reference galaxy cluster to each of the other galaxy clusters. Measure and record the wavelength of each wavy line. Inflate the balloon. Measure and record the distances between galaxy clusters and the wavelengths of the wavy lines.

Teaching Strategies Have a balloon already marked so students can compare their balloons to it.

Troubleshooting Have students blow up their balloons and let them deflate prior to beginning the exercise.

Expansion of the Universe

Real-World Problem

You have read that the universe is expanding. In fact, recent calculations indicate that it is expanding more quickly now than it did in the past. Astronomers are able to measure this expansion because it stretches the wavelengths of light coming from distant objects. Can you make a model that demonstrates how this happens?

Make a Model

1. Work in teams of two or more. **Collect** all needed materials.
2. Sketch an image on the balloon slightly inflated. **Model** the positions of galaxy clusters by placing three or four dots at four different locations and different distances apart on the surface of the balloon. Mark the locations R (for reference), A, B, and C.
3. Make a table for data.
4. Check to see if the binder clip can hold air in the balloon long enough for you to make measurements and to draw on the balloon.
5. Obtain your teacher's approval of your sketches and data table before proceeding.

Test Your Model

1. Slightly inflate your balloon so that it is not very big.
2. Use the binder clip to temporarily seal the balloon (or have your partner hold it closed). Do not tie it.
3. **Measure** the distance from your reference galaxy cluster (R) to each of the other galaxy clusters and record these distances on your data table.

Data

Location	First Distance Measurement	Second Distance Measurement	Change in Distance	First λ Measurement	Second λ Measurement	Change in λ
A						
B						
C						

Fun Fact

If the accelerated expansion of the universe continues, eventually the only stars that will be visible to observers on Earth will be those in the Milky Way Galaxy and those in the galaxies of the Local Group.

Differentiated Instruction

Physically Challenged If students cannot manipulate the binder clips, have them work with other students. A physically challenged student can hold the balloon after the clip has been attached or the balloon has been tied shut. A physically challenged student could inflate the balloon while another student attaches the binder clip or ties the end of the balloon shut. L2

Using Scientific Methods

4. Draw a wavy line from your reference galaxy cluster to each of the other galaxy clusters marked to represent the wavelength (λ) of light coming from each galaxy cluster. Measure and record the wavelength of each wavy line.
5. Inflate your balloon farther (be careful not to inflate it too much). Replace the binder clip or tie the end shut.
6. **Measure** and record the distances from your reference galaxy cluster to each of the other galaxy clusters.
7. **Measure** and record the wavelength of each wavy line on your inflated model.

Analyze Your Data

1. **Calculate** the change in distance and the change in wavelength for each galaxy cluster and record it on your data table.
2. **Analyze** whether objects moved on your model or whether your entire model expanded.

Conclude and Apply

1. **Explain** any changes in distance or wavelength noted.
2. **Conclude** whether the objects moved apart because of their individual motions or because the model expanded.
3. **Infer** how measurements on your model can be related to measurements of the universe.

Communicating Your Data

Enter the data from your model on a table that shows the data from all teams of students.

LAB 841

Communicating Your Data

Encourage students to perform the exercise more than once to check their data. Have them discuss their results with another team and find out if that team obtained similar data. If not, have them discuss possible reasons for any differences noted.

Test Your Model

Expected Outcome Students will use expansion of the balloon as a model of the expansion of the universe.

Analyze Your Data

1. Answers will vary depending on the size of the balloon, how much they inflate it, and where they locate their galaxy clusters.
2. Individual points representing the galaxy clusters did not move on the balloon, the entire model of the universe expanded.

Conclude and Apply

1. As the model expanded, the distances between the galaxy clusters increased. The wavelength of light traveling between galaxy clusters increased.
2. The galaxy clusters moved apart because the entire model expanded.
3. If the universe is thought of as a balloon, the fabric of the universe is the skin of the balloon. Distances and wavelength of light would increase in the universe just as the measurement of these factors increased on the balloon model.

Assessment

Process Ask students to hypothesize as to what would happen if the universe stopped expanding and started to shrink. **Possible answer:** The distances between galaxy clusters and the wavelength traveling from between galaxy clusters would decrease. Use **Performance Assessment in the Science Classroom**, p. 93. [L2]

Understanding Literature

Imagery The primary sense evoked by Sara Teasdale in this poem is sight. The reader is aware of the darkness and the varied colors of stars that are seen moving steadily across the sky. The senses of sound and smell are also triggered as she describes the pine trees as being "still" and having a "spicy" smell.

Respond to the Reading

1. Teasdale writes that the stars have beating hearts. She describes their movement across the sky as a march up a great hill.
2. The author expresses feelings of awe and gratitude for the beauty she witnesses. The tone is reverence.
3. **Linking Science and Writing** Review stellar characteristics with students, including the process of nuclear fusion, the relationship between temperature and color, and the life cycle of stars. Review the connection between Earth's rotation and the apparent movement of stars.

Light Pollution Unless you have viewed the stars on a clear, dark night like the author, you may not fully understand her emotion. Astronomers are very concerned about light pollution. Every observatory in the southwest is affected, as city lights brighten skies. [L2]

Stars

Sara Teasdale

*Alone in the night
On a dark hill
With pines around me
Spicy and still,*

*And a heaven full of stars
Over my head,
White and topaz
And misty red;*

*Myriads with beating
Hearts of fire
That aeons
Cannot vex or tire;*

*Up the dome of heaven
Like a great hill,
I watch them marching
Stately and still,*

*And I know that I
Am honored to be
Witness
Of so much majesty.*

Understanding Literature

Imagery Imagery refers to how a literary work invites the reader to see, hear, smell, touch, or taste something in his mind. Authors often use related images throughout a work, encouraging the reader to consider the subject using more than one sense. Of what specific senses does this poet make the reader aware?

Respond to the Reading

1. How does the author use personification to make the stars in the poem seem alive?
2. Tone refers to the overall mood of a literary work. Describe the tone of this poem.
3. **Linking Science and Writing** The poet refers to the color, age, energy source, and apparent movement of stars. Write a paragraph relating what you have learned about these properties to how they are mentioned in the poem.

On a clear, dark night, it is possible to see as many as 1,500 stars with the unaided eye. However, this number is far lower because of light pollution. Light from houses, shopping areas, signs, and street lights floods the sky, making it difficult to see the stars. Inside major cities, fewer than 50 stars may be visible in the night sky.

Resources for Teachers and Students

Nightwatch: A Practical Guide to Viewing the Universe, by Terence Dickinson, Firefly Books, Ltd, 1998.

The Book of Constellations: Discover the Secrets in the Stars, by Robin Kerrod, Barron's Educational Series, 2002.

Reviewing Main Ideas

Section 1 Observing the Universe

1. Constellations are patterns of stars that resemble things familiar to the observer.
2. Optical telescopes collect visible light and magnify viewed objects.
3. A refracting telescope uses lenses to collect light and magnify the image, and a reflecting telescope uses a mirror to collect light and a lens to magnify the image.
4. A radio telescope collects and amplifies radio waves.

Section 2 Evolution of Stars

1. Stars form from a large cloud of gas, ice, and dust, called a nebula like the one shown here. When the temperature inside the contracting nebula reaches 10 million K, fusion begins, and a star is born.

2. Stars are classified as main sequence stars, giants, and white dwarfs on the H-R diagram.
3. When a star reaches stellar equilibrium it is considered a main sequence star. When the hydrogen fuel is depleted, a star loses equilibrium and evolves into a giant or supergiant.
4. After losing its outer layers, a giant becomes a white dwarf. A supergiant can evolve into a neutron star or a black hole.
5. The Sun's energy is produced at its core by nuclear fusion.

Section 3 Galaxies and the Milky Way

1. A galaxy is a large group of stars, gas, and dust held together by gravity. The Local Group of galaxies is a cluster that contains the Milky Way Galaxy.
2. The three main types of galaxies are elliptical, irregular, and spiral as shown here.
3. Astronomers believe that galaxies form by absorbing or merging with smaller objects. They continue to evolve by colliding or merging with other galaxies.
4. The Milky Way galaxy is about 100,000 light-years across and the Sun lies about 26,000 light-years from its center.

Section 4 Cosmology

1. The big bang theory is the most accepted theory of how the universe began.
2. The universe is 13.7 billion years old and appears to be expanding faster now than in the past.
3. The Hubble red shift is caused by the expansion of space, not the movement of galaxies.

FOLDABLES™ Use the Foldable that you made at the beginning of this chapter to help you review what you learned about cosmology.

CHAPTER STUDY GUIDE 843

Identifying Misconceptions

After students have done the activity on page F at the beginning of the chapter and completed the chapter, have them perform this activity.

Materials various-sized plastic or paper drinking cups

Procedure Randomly place the cups of different sizes over the top of a large flat table. Have a student close one eye and kneel at one end of the

table. Ask them to identify which cups seem to be close to each other.

Expected Outcome Students using only one eye will lose some of their ability to judge distance and will select several cups that look like they are next to each other only to discover that they can be quite far away from each other on the table, just as stars can be in the galaxy. [L2]

Assess

Reviewing Main Ideas

Summary statements can be used by students to review the major concepts of the chapter.

★ FCAT Vocabulary

Match the correct vocabulary word(s) with each definition given below.

- patterns of stars
- an optical telescope that uses a mirror to collect light
- the distance light travels in one year
- plotted from the upper left to the lower right on the H-R diagram
- star in which the core contracts and outer layers expand and cool
- layer of the Sun from which light is emitted
- dark, cooler areas on the Sun's photosphere
- large group of stars, gas, and dust held together by gravity
- spiral galaxy that contains the solar system
- study of the evolution of the universe

Checking Concepts

Choose the word or phrase that best answers the question.

- Which telescope uses lenses to collect light and form an image?
A) adaptive C) reflecting
B) radio D) refracting

- Which form of energy are optical telescopes used to study?
A) infrared radiation
B) radio waves
C) visible light
D) X rays
- Which magnifies the image in a telescope?
A) eyepiece C) focus
B) focal length D) objective
- Which is the most common type of star in the universe?
A) giant C) red dwarf
B) neutron D) white dwarf
- Which forms from a star that is over 25 times the mass of the Sun?
A) black hole C) neutron star
B) giant star D) white dwarf
- Which is a feature of the Sun that can reach 100 million K?
A) CME C) prominence
B) flare D) sunspot

Use the illustration below to answer question 17.

- Which type of galaxy is most common?
A) barred spiral
B) dwarf elliptical
C) irregular
D) spiral
- Which is the most accepted theory of how the universe formed?
A) big bang C) oscillating
B) collision D) steady state

19. Which adds to the gravity of a galaxy, but cannot be seen or detected?
- dark energy
 - dark matter
 - regular energy
 - regular matter

Interpreting Graphics

20. Make a table summarizing the absolute brightness (magnitude) and temperatures of stars on this H-R diagram.

Hertzsprung-Russell Diagram for Stars

21. Draw and label scale models of the following stars: the Sun; Antares, 500 times larger than the Sun; and Sirius B 0.01 times the Sun's diameter.
22. Draw and label a concept map showing the life history of a star like the Sun.
23. Draw and label the parts in a reflecting telescope.

Thinking Critically

24. Explain how energy created in the core of the Sun is eventually emitted from the photosphere.
25. Compare and contrast elliptical, irregular, and spiral galaxies.

26. Discuss the benefits of using a radio telescope.
27. Explain why high sunspot activity on the Sun can affect Earth's magnetic field.
28. Explain how the Sun's position in the Milky Way affects how we perceive our galaxy.

Applying Math

29. Solve One-Step Equations Use the equation $M_p = f_o/f_e$ to determine the magnifying power of a telescope in which the focal lengths of the objective and eyepiece are 1500 mm and 9 mm, respectively.

Use the illustration below to answer question 30.

30. A solar storm that took place in 1859 is called "the perfect storm," because of its great power. The diagram shows the relative destructive power of some solar storms. Using this diagram, calculate approximately how much more destructive was the solar storm of 1859 than the one of 1989.
31. Calculate how long ago the light we see today left a star that is 25 light-years away. Calculate the distance in km to that star.

Interpreting Graphics

20.

H-R Diagram Summary		
Star Type	Absolute Brightness	Temperature
Giant	High	Low
Main sequence	Varies with mass	Varies with mass
White dwarf	Low	High

21. Antares should be about 7.5 m in diameter. The Sun should be about 1.5 cm and Sirius B should be about 1.5 mm.
22. Student maps should include the following: nebula, main sequence, giant, white dwarf, black dwarf.
23. Student drawings should show and should label the objective, the eyepiece, the focus, and the focal length.

Thinking Critically

24. Energy emitted at the core of the Sun radiates through the transparent radiation layer and then is transferred to the surface by convection cells.
25. All are families of stars, dust, and gas held together by gravity. Elliptical galaxies look like round or elliptical balls, spiral galaxies have spiral arms, and irregular galaxies have no regular structure.
26. Radio telescopes can be used during the day and in all kinds of weather.
27. Sunspots are magnetic storms on the Sun and increase the amount of charged material in the solar wind that can affect Earth's magnetic field.
28. The Sun's position within one of its spiral arms obscures visibility of the entire Milky Way.

Applying Math

Math Standards

National: 2, 9

Florida: MA.B.1.4.2

29. $M_p = 167$
30. about three times
31. 25 years; 237.5 trillion km

Standardized Test Practice Answer Sheet

Multiple Choice

1. ☐ A ☐ B ☐ C ☐ D

2. ☐ A ☐ B ☐ C ☐ D

3. ☐ A ☐ B ☐ C ☐ D

Gridded Response

1. 120	2. 52.8 m ²
3. 120	4. 52.8 m ²
5. 120	6. 52.8 m ²
7. 120	8. 52.8 m ²
9. 120	10. 52.8 m ²
11. 120	12. 52.8 m ²
13. 120	14. 52.8 m ²
15. 120	16. 52.8 m ²

Go On

Multiple Choice

1. D
2. A
3. B
4. D
5. D
6. A

Gridded Response

7. 120
8. 52.8 m²

Record your answers on the answer sheet provided by your teacher or on a sheet of paper.
The assessed Florida Benchmark appears above the question.

Multiple Choice

1. What is used as an objective in a reflecting telescope?
 - A. antenna
 - B. camera
 - C. lens
 - D. mirror

Use the photo below to answer question 2.

2. Which type of telescope is shown?
 - A. optical
 - B. radio
 - C. ultraviolet
 - D. X-ray

Test-Taking Tip

Concentrate Stay focused during the test and don't rush, even if you notice that other students are finishing the test early.

3. Which group contains most stars on the H-R diagram?
 - A. giant
 - B. main sequence
 - C. supergiant
 - D. white dwarf

SC.2.4.1

4. Which stage of stellar evolution occurs when the outer layers escape, leaving behind the hot core?
 - A. black hole
 - B. giant
 - C. main sequence
 - D. white dwarf

Use the illustration below to answer question 5.

SC.2.4.4

5. What occurs inside a main sequence star?
 - A. Energy from fusion exceeds gravity.
 - B. Fusion shuts down.
 - C. Gravity exceeds energy from fusion.
 - D. It attains stellar equilibrium.

6. Which may be responsible for the accelerating expansion of the universe?
- dark energy
 - dark matter
 - regular energy
 - regular matter

Gridded Response

7. If the focal length of a telescope objective is 2,400 mm and the focal length of the eyepiece is 20 mm, what is the magnifying power of the telescope?
8. Use this equation, $A = \pi r^2$. What is the area in square meters of one of the four 8.2-meter reflectors in the *Very Large Telescope*?

Short Response

Use the illustration below to answer question 9.

9. Describe the structure of the Sun's interior.

SC.E.2.4.6

10. What does a spectroscope do to starlight that enables astronomers to determine the star's composition?

SC.E.2.4.6

11. What does the H-R diagram show about the stars plotted on it?

12. What are coronal mass ejections?

SC.E.2.4.2

13. What is the Local Group?

SC.E.2.4.5

14. How do astronomers think that galaxies like the Milky Way formed?

15. What is cosmology?

SC.E.2.4.6

16. Why have astronomers proposed the existence of dark energy in the universe?

Extended Response

Use the photo below to help answer question 17.

SC.E.2.4.1

17. **PART A** What are the evolutionary stages of a star like the Sun?

- PART B** What are the evolutionary stages of a star more than eight times the mass of the Sun?

Short Response

12. Coronal mass ejections (CMEs) are large bubble of ionized gas are emitted from the Sun.
13. A relatively small cluster of about 45 galaxies that includes the Milky Way Galaxy. Most galaxies in the Local Group are dwarf elliptical galaxies.
14. Most astronomers believe that relatively nearby galaxies grew by absorbing or merging with other smaller objects.
15. The study how the universe began, how it continues to evolve, and what it is made of.
16. The existence of dark energy is used to explain the apparent accelerating expansion of the universe.

Extended Response

17. **Part A:** After a star like the Sun reaches the main sequence, it will eventually evolve to a giant star, then a planetary nebula. After that it will evolve to a white dwarf and end as a black dwarf.
- Part B:** A star eight times more massive than the Sun will become a main sequence star quicker and stay there for a much shorter period. After main sequence, it will evolve into a supergiant, a neutron star, and eventually a black hole.

Rubrics

For more help evaluating Short- and Extended-Response questions, see the rubrics on p. 9T.

Short Response

10. A spectroscope disperses the light into its component wavelengths, producing a spectrum. Astronomers use the contained wavelengths to determine the chemical composition of the star from which the light was collected.
11. The temperature or color of the star is plotted against its absolute magnitude.
9. The central area of the Sun is the core where fusion occurs. Above the core, energy radiates outward through the radiation layer. Energy moves through the convection layer to the Sun's surface by convection.

Scientific Methods

Scientists use an orderly approach called the scientific method to solve problems. This includes organizing and recording data so others can understand them. Scientists use many variations in this method when they solve problems.

Identify a Question

The first step in a scientific investigation or experiment is to identify a question to be answered or a problem to be solved. For example, you might ask which gasoline is the most efficient.

Gather and Organize Information

After you have identified your question, begin gathering and organizing information. There are many ways to gather information, such as researching in a library, interviewing those knowledgeable about the subject, testing, and working in the laboratory and field. Fieldwork is investigations and observations done outside of a laboratory.

Researching Information Before moving in a new direction, it is important to gather the information that already is known about the subject. Start by asking yourself questions to determine exactly what you need to know. Then you will look for the information in various reference sources, like the student is doing in **Figure 1**. Some sources may include textbooks, encyclopedias, government documents, professional journals, science magazines, and the Internet. Always list the sources of your information.

Figure 1 The Internet can be a valuable research tool.

Evaluate Sources of Information Not all sources of information are reliable. You should evaluate all your sources of information, and use only those you know to be dependable. For example, if you are researching ways to make homes more energy efficient, a site written by the U.S. Department of Energy would be more reliable than a site written by a company that is trying to sell a new type of weatherproofing material. Also, remember that research always is changing. Consult the most current resources available to you. For example, a 1985 resource about saving energy would not reflect the most recent findings.

Sometimes scientists use data that they did not collect themselves, or conclusions drawn by other researchers. These data must be evaluated carefully. Ask questions about how the data were obtained, if the investigation was carried out properly, and if it has been duplicated exactly with the same results. Would you reach the same conclusion from the data? Only when you have confidence in the data can you believe it is true and feel comfortable using it.

Interpret Scientific Illustrations As you research a topic in science, you will see drawings, diagrams, and photographs to help you understand what you read. Some illustrations are included to help you understand an idea that you can't see easily by yourself, like the tiny particles in an atom in **Figure 2**. A drawing helps many people to remember details more easily and provides examples that clarify difficult concepts or give additional information about the topic you are studying. Most illustrations have labels or a caption to identify or to provide more information.

Figure 2 This drawing shows an atom of carbon with its six protons, six neutrons, and six electrons.

Concept Maps One way to organize data is to draw a diagram that shows relationships among ideas (or concepts). A concept map can help make the meanings of ideas and terms more clear, and help you understand and remember what you are studying. Concept maps are useful for breaking large concepts down into smaller parts, making learning easier.

Network Tree A type of concept map that not only shows a relationship, but how the concepts are related is a network tree, shown in **Figure 3**. In a network tree, the words are written in the ovals, while the description of the type of relationship is written across the connecting lines.

When constructing a network tree, write down the topic and all major topics on separate pieces of paper or notecards. Then arrange them in order from general to specific. Branch the related concepts from the major concept and describe the relationship on the connecting line. Continue to more specific concepts until finished.

Figure 3 A network tree shows how concepts or objects are related.

Events Chain Another type of concept map is an events chain. Sometimes called a flow chart, it models the order or sequence of items. An events chain can be used to describe a sequence of events, the steps in a procedure, or the stages of a process.

When making an events chain, first find the one event that starts the chain. This event is called the initiating event. Then, find the next event and continue until the outcome is reached, as shown in **Figure 4**.

Figure 4 Events-chain concept maps show the order of steps in a process or event. This concept map shows how a sound makes an echo.

Cycle Map A specific type of events chain is a cycle map. It is used when the series of events do not produce a final outcome, but instead relate back to the beginning event, such as in **Figure 5**. Therefore, the cycle repeats itself.

To make a cycle map, first decide what event is the beginning event. This is also called the initiating event. Then list the next events in the order that they occur, with the last event relating back to the initiating event. Words can be written between the events that describe what happens from one event to the next. The number of events in a cycle map can vary, but usually contain three or more events.

Figure 5 A cycle map shows events that occur in a cycle.

Spider Map A type of concept map that you can use for brainstorming is the spider map. When you have a central idea, you might find that you have a jumble of ideas that relate to it but are not necessarily clearly related to each other. The spider map on sound in **Figure 6** shows that if you write these ideas outside the main concept, then you can begin to separate and group unrelated terms so they become more useful.

Figure 6 A spider map allows you to list ideas that relate to a central topic but not necessarily to one another.

Figure 7 This Venn diagram compares and contrasts two substances made from carbon.

Venn Diagram To illustrate how two subjects compare and contrast you can use a Venn diagram. You can see the characteristics that the subjects have in common and those that they do not, shown in **Figure 7**.

To create a Venn diagram, draw two overlapping ovals that are big enough to write in. List the characteristics unique to one subject in one oval, and the characteristics of the other subject in the other oval. The characteristics in common are listed in the overlapping section.

Make and Use Tables One way to organize information so it is easier to understand is to use a table. Tables can contain numbers, words, or both.

To make a table, list the items to be compared in the first column and the characteristics to be compared in the first row. The title should clearly indicate the content of the table, and the column or row heads should be clear. Notice that in **Table 1** the units are included.

Table 1 Recyclables Collected During Week			
Day of Week	Paper (kg)	Aluminum (kg)	Glass (kg)
Monday	5.0	4.0	12.0
Wednesday	4.0	1.0	10.0
Friday	2.5	2.0	10.0

Make a Model One way to help you better understand the parts of a structure, the way a process works, or to show things too large or small for viewing is to make a model. For example, an atomic model made of a plastic-ball nucleus and pipe-cleaner electron shells can help you visualize how the parts of an atom relate to each other. Other types of models can be devised on a computer or represented by equations.

Form a Hypothesis

A possible explanation based on previous knowledge and observations is called a hypothesis. After researching gasoline types and recalling previous experiences in your family's car you form a hypothesis—our car runs more efficiently because we use premium gasoline. To be valid, a hypothesis has to be something you can test by using an investigation.

Predict When you apply a hypothesis to a specific situation, you predict something about that situation. A prediction makes a statement in advance, based on prior observation, experience, or scientific reasoning. People use predictions to make everyday decisions. Scientists test predictions by performing investigations. Based on previous observations and experiences, you might form a prediction that cars are more efficient with premium gasoline. The prediction can be tested in an investigation.

Design an Experiment A scientist needs to make many decisions before beginning an investigation. Some of these include: how to carry out the investigation, what steps to follow, how to record the data, and how the investigation will answer the question. It also is important to address any safety concerns.

Test the Hypothesis

Now that you have formed your hypothesis, you need to test it. Using an investigation, you will make observations and collect data, or information. This data might either support or not support your hypothesis. Scientists collect and organize data as numbers and descriptions.

Follow a Procedure In order to know what materials to use, as well as how and in what order to use them, you must follow a procedure. **Figure 8** shows a procedure you might follow to test your hypothesis.

Procedure

1. Use regular gasoline for two weeks.
2. Record the number of kilometers between fill-ups and the amount of gasoline used.
3. Switch to premium gasoline for two weeks.
4. Record the number of kilometers between fill-ups and the amount of gasoline used.

Figure 8 A procedure tells you what to do step by step.

Identify and Manipulate Variables and Controls In any experiment, it is important to keep everything the same except for the item you are testing. The one factor you change is called the independent variable. The change that results is the dependent variable. Make sure you have only one independent variable, to assure yourself of the cause of the changes you observe in the dependent variable. For example, in your gasoline experiment the type of fuel is the independent variable. The dependent variable is the efficiency.

Many experiments also have a control—an individual instance or experimental subject for which the independent variable is not changed. You can then compare the test results to the control results. To design a control you can have two cars of the same type. The control car uses regular gasoline for four weeks. After you are done with the test, you can compare the experimental results to the control results.

Collect Data

Whether you are carrying out an investigation or a short observational experiment, you will collect data, as shown in **Figure 9**. Scientists collect data as numbers and descriptions and organize it in specific ways.

Observe Scientists observe items and events, then record what they see. When they use only words to describe an observation, it is called qualitative data. Scientists' observations also can describe how much there is of something. These observations use numbers, as well as words, in the description and are called quantitative data. For example, if a sample of the element gold is described as being "shiny and very dense" the data are qualitative. Quantitative data on this sample of gold might include "a mass of 30 g and a density of 19.3 g/cm^3 ."

Figure 9 Collecting data is one way to gather information directly.

Figure 10 Record data neatly and clearly so it is easy to understand.

When you make observations you should examine the entire object or situation first, and then look carefully for details. It is important to record observations accurately and completely. Always record your observations immediately as you make them, so you do not miss details or make a mistake when recording results from memory. Never put unidentified observations on scraps of paper. Instead they should be recorded in a notebook, like the one in **Figure 10**. Write your data neatly so you can easily read it later. At each point in the experiment, record your observations and label them. That way, you will not have to determine what the figures mean when you look at your notes later. Set up any tables that you will need to use ahead of time, so you can record any observations right away. Remember to avoid bias when collecting data by not including personal thoughts when you record observations. Record only what you observe.

Estimate Scientific work also involves estimating. To estimate is to make a judgment about the size or the number of something without measuring or counting. This is important when the number or size of an object or population is too large or too difficult to accurately count or measure.

Sample Scientists may use a sample or a portion of the total number as a type of estimation. To sample is to take a small, representative portion of the objects or organisms of a population for research. By making careful observations or manipulating variables within that portion of the group, information is discovered and conclusions are drawn that might apply to the whole population. A poorly chosen sample can be unrepresentative of the whole. If you were trying to determine the rainfall in an area, it would not be best to take a rainfall sample from under a tree.

Measure You use measurements every day. Scientists also take measurements when collecting data. When taking measurements, it is important to know how to use measuring tools properly. Accuracy also is important.

Length To measure length, the distance between two points, scientists use meters. Smaller measurements might be measured in centimeters or millimeters.

Length is measured using a metric ruler or meterstick. When using a metric ruler, line up the 0-cm mark with the end of the object being measured and read the number of the unit where the object ends. Look at the metric ruler shown in **Figure 11**. The centimeter lines are the long, numbered lines, and the shorter lines are millimeter lines. In this instance, the length would be 4.50 cm.

Figure 11 This metric ruler has centimeter and millimeter divisions.

Mass The SI unit for mass is the kilogram (kg). Scientists can measure mass using units formed by adding metric prefixes to the unit gram (g), such as milligram (mg). To measure mass, you might use a triple-beam balance similar to the one shown in **Figure 12**. The balance has a pan on one side and a set of beams on the other side. Each beam has a rider that slides on the beam.

When using a triple-beam balance, place an object on the pan. Slide the largest rider along its beam until the pointer drops below zero. Then move it back one notch. Repeat the process for each rider proceeding from the larger to smaller until the pointer swings an equal distance above and below the zero point. Sum the masses on each beam to find the mass of the object. Move all riders back to zero when finished.

Instead of putting materials directly on the balance, scientists often take a tare of a container. A tare is the mass of a container into which objects or substances are placed for measuring their masses. To mass objects or substances, find the mass of a clean container. Remove the container from the pan, and place the object or substances in the container. Find the mass of the container with the materials in it. Subtract the mass of the empty container from the mass of the filled container to find the mass of the materials you are using.

Figure 12 A triple-beam balance is used to determine the mass of an object.

Figure 13 Graduated cylinders measure liquid volume.

Liquid Volume To measure liquids, the unit used is the liter (L). When a smaller unit is needed, scientists might use a milliliter (mL). Because a milliliter takes up the volume of a cube measuring 1 cm on each side it also can be called a cubic centimeter ($\text{cm}^3 = \text{cm} \times \text{cm} \times \text{cm}$).

You can use beakers and graduated cylinders to measure liquid volume. A graduated cylinder, shown in **Figure 13**, is marked from bottom to top in milliliters. In the lab, you might use a 10-mL graduated cylinder or a 100-mL graduated cylinder. When measuring liquids, notice that the liquid has a curved surface. Look at the surface at eye level, and measure the bottom of the curve. This is called the meniscus. The graduated cylinder in **Figure 13** contains 79.0 mL, or 79.0 cm^3 , of a liquid.

Temperature Scientists often measure temperature using the Celsius scale. Pure water has a freezing point of 0°C and boiling point of 100°C . The unit of measurement is degrees Celsius. Two other scales often used are the Fahrenheit and Kelvin scales.

Figure 14 A thermometer measures the temperature of an object.

Scientists use a thermometer to measure temperature. Most thermometers in a laboratory are glass tubes with a bulb at the bottom end containing a liquid such as colored alcohol. The liquid rises or falls with a change in temperature. To read a glass thermometer like the thermometer in **Figure 14**, rotate it slowly until a red line appears. Read the temperature where the red line ends.

Form Operational Definitions An operational definition defines an object by how it functions, works, or behaves. For example, when you are playing hide and seek and a tree is home base, you have created an operational definition for a tree.

Objects can have more than one operational definition. For example, a ruler can be defined as a tool that measures the length of an object (how it is used). It can also be a tool with a series of marks used as a standard when measuring (how it works).

Analyze the Data

To determine the meaning of your observations and investigation results, you will need to look for patterns in the data. Then you must think critically to determine what the data mean. Scientists use several approaches when they analyze the data they have collected and recorded. Each approach is useful for identifying specific patterns.

Interpret Data The word *interpret* means “to explain the meaning of something.” When analyzing data from an experiment, try to find out what the data show. Identify the control group and the test group to see whether or not changes in the independent variable have had an effect. Look for differences in the dependent variable between the control and test groups.

Classify Sorting objects or events into groups based on common features is called classifying. When classifying, first observe the objects or events to be classified. Then select one feature that is shared by some members in the group, but not by all. Place those members that share that feature in a subgroup. You can classify members into smaller and smaller subgroups based on characteristics. Remember that when you classify, you are grouping objects or events for a purpose. Keep your purpose in mind as you select the features to form groups and subgroups.

Compare and Contrast Observations can be analyzed by noting the similarities and differences between two more objects or events that you observe. When you look at objects or events to see how they are similar, you are comparing them. Contrasting is looking for differences in objects or events.

Recognize Cause and Effect A cause is a reason for an action or condition. The effect is that action or condition. When two events happen together, it is not necessarily true that one event caused the other. Scientists must design a controlled investigation to recognize the exact cause and effect.

Draw Conclusions

When scientists have analyzed the data they collected, they proceed to draw conclusions about the data. These conclusions are sometimes stated in words similar to the hypothesis that you formed earlier. They may confirm a hypothesis, or lead you to a new hypothesis.

Infer Scientists often make inferences based on their observations. An inference is an attempt to explain observations or to indicate a cause. An inference is not a fact, but a logical conclusion that needs further investigation. For example, you may infer that a fire has caused smoke. Until you investigate, however, you do not know for sure.

Apply When you draw a conclusion, you must apply those conclusions to determine whether the data support the hypothesis. If your data do not support your hypothesis, it does not mean that the hypothesis is wrong. It means only that the result of the investigation did not support the hypothesis. Maybe the experiment needs to be redesigned, or some of the initial observations on which the hypothesis was based were incomplete or biased. Perhaps more observation or research is needed to refine your hypothesis. A successful investigation does not always come out the way you originally predicted.

Avoid Bias Sometimes a scientific investigation involves making judgments. When you make a judgment, you form an opinion. It is important to be honest and not to allow any expectations of results to bias your judgments. This is important throughout the entire investigation, from researching to collecting data to drawing conclusions.

Communicate

The communication of ideas is an important part of the work of scientists. A discovery that is not reported will not advance the scientific community's understanding or knowledge. Communication among scientists also is important as a way of improving their investigations.

Scientists communicate in many ways, from writing articles in journals and magazines that explain their investigations and experiments, to announcing important discoveries on television and radio. Scientists also share ideas with colleagues on the Internet or present them as lectures, like the student is doing in **Figure 15**.

Figure 15 A student communicates to his peers about his investigation.

SAFETY SYMBOLS

SAFETY SYMBOLS		HAZARD	EXAMPLES	PRECAUTION	REMEDY
DISPOSAL		Special disposal procedures need to be followed.	certain chemicals, living organisms	Do not dispose of these materials in the sink or trash can.	Dispose of wastes as directed by your teacher.
BIOLOGICAL		Organisms or other biological materials that might be harmful to humans	bacteria, fungi, blood, unpreserved tissues, plant materials	Avoid skin contact with these materials. Wear mask or gloves.	Notify your teacher if you suspect contact with material. Wash hands thoroughly.
EXTREME TEMPERATURE		Objects that can burn skin by being too cold or too hot	boiling liquids, hot plates, dry ice, liquid nitrogen	Use proper protection when handling.	Go to your teacher for first aid.
SHARP OBJECT		Use of tools or glassware that can easily puncture or slice skin	razor blades, pins, scalpels, pointed tools, dissecting probes, broken glass	Practice common-sense behavior and follow guidelines for use of the tool.	Go to your teacher for first aid.
FUME		Possible danger to respiratory tract from fumes	ammonia, acetone, nail polish remover, heated sulfur, moth balls	Make sure there is good ventilation. Never smell fumes directly. Wear a mask.	Leave foul area and notify your teacher immediately.
ELECTRICAL		Possible danger from electrical shock or burn	improper grounding, liquid spills, short circuits, exposed wires	Double-check setup with teacher. Check condition of wires and apparatus.	Do not attempt to fix electrical problems. Notify your teacher immediately.
IRRITANT		Substances that can irritate the skin or mucous membranes of the respiratory tract	pollen, moth balls, steel wool, fiberglass, potassium permanganate	Wear dust mask and gloves. Practice extra care when handling these materials.	Go to your teacher for first aid.
CHEMICAL		Chemicals can react with and destroy tissue and other materials	bleaches such as hydrogen peroxide; acids such as sulfuric acid, hydrochloric acid; bases such as ammonia, sodium hydroxide	Wear goggles, gloves, and an apron.	Immediately flush the affected area with water and notify your teacher.
TOXIC		Substance may be poisonous if touched, inhaled, or swallowed.	mercury, many metal compounds, iodine, poinsettia plant parts	Follow your teacher's instructions.	Always wash hands thoroughly after use. Go to your teacher for first aid.
FLAMMABLE		Flammable chemicals may be ignited by open flame, spark, or exposed heat.	alcohol, kerosene, potassium permanganate	Avoid open flames and heat when using flammable chemicals.	Notify your teacher immediately. Use fire safety equipment if applicable.
OPEN FLAME		Open flame in use, may cause fire.	hair, clothing, paper, synthetic materials	Tie back hair and loose clothing. Follow teacher's instruction on lighting and extinguishing flames.	Notify your teacher immediately. Use fire safety equipment if applicable.

Eye Safety

Proper eye protection should be worn at all times by anyone performing or observing science activities.

Clothing Protection

This symbol appears when substances could stain or burn clothing.

Animal Safety

This symbol appears when safety of animals and students must be ensured.

Handwashing

After the lab, wash hands with soap and water before removing goggles.

Introduction to Science Safety

Confucius, an ancient and well-known Chinese philosopher, is credited with a statement that could serve as a legacy of all types of human wisdom. It seems especially appropriate for the active learning you will experience in this science program.

“I hear and I forget, I see and I remember, I do and I understand.”

This is the basis for the safety routine that will be used in all the labs in this book. It is assumed that you will use all of your senses as you “experience” the labs. However, with such experience comes the potential for injury. The purpose of this section of the book is to help keep you safe by involving you in the safety process.

How will your teacher help?

It will be your teacher’s responsibility to decide which science labs are safe and appropriate for you. Your teacher will identify the hazards involved in each activity and likely will ask for your assistance for ways to reduce the dangers as much as possible. He or she will involve you regularly in safety discussions about your understanding of the actual and potential dangers and the safety measures needed to keep everyone safe. Ideally, this will become a habit with each lab in which you take part.

Your teacher also will explain the safety features of your room as well as the most important safety equipment and routines for addressing safety issues. He or she will also require that you complete a *Student Lab-Safety Form* for each lab to make certain you are prepared to perform the lab safely.

Your teacher will review your comments, make corrections, and sign or initial this form **BEFORE** you will be permitted to begin the lab.

The ultimate purpose of the safety discussions and the *Student Lab-Safety Form* will be to **help you take some responsibility for your own safety** and to help you to develop good habits when you prepare and perform science experiments and labs.

How can you help?

Since your teacher cannot anticipate every safety hazard that might occur and he or she cannot be everywhere in the room at the same time, you need to take some responsibility for your own safety. The following general information should apply to nearly every science lab in which you will be involved as part of this class.

Adapted from Gerlovich, et al. (2004). The Total Science Safety System D. JaKel, Inc. <http://www.netins.net/showcase/jakel>. Used with Permission

You must:

- Review any *Safety Symbols* in the labs and be certain that you know what they mean.
- Follow all teacher instructions for safety and make certain that you understand all the hazards related to the labs you are about to do.
- Be able to explain the purpose of the lab.
- Be able to explain, or demonstrate, all reasonable emergency procedures, such as:
 - how to evacuate the room during emergencies;
 - how to react to any chemical emergencies;
 - how to deal with fire emergencies;
 - how to perform a scientific investigation safely;
 - how to anticipate some safety concerns and be prepared to address them;
 - how to use equipment properly and safely.

- Be able to locate and use all safety equipment as directed by your teacher, such as:
 - fire extinguishers;
 - fire blankets;
 - eye protective equipment (goggles, safety glasses, face shield);
 - eyewash;
 - drench shower.
- Complete the Student Lab-Safety Form before starting any science lab.
- Ask questions about any safety concerns that you might have **BEFORE** starting any lab of science investigation.

Remember! Your teacher will review your comments, make corrections, and sign or initial the *Student Lab-Safety Form* **BEFORE** you will be permitted to begin the lab. A copy of this form appears below.

Student Lab-Safety Form

Student Name _____ Date _____	Teacher Approval Initials _____ Date of Approval _____
I understand from my teacher that you understand the safety concerns of this lab, the emergency procedures must be answered after the teacher explains the information to you. You must review and sign this form before you can proceed with the lab. 1. How would you describe what you will be doing during this lab? 2. What are the safety concerns in this lab (explained by your teacher)? 3. What additional safety concerns or questions do you have?	

Reduce Fractions

$$\frac{66 \div 6}{90 \div 6} = \frac{11}{15}$$

Add and Subtract Fractions

$$\frac{4}{9} + \frac{2}{9} = \frac{6}{9}$$

$$\frac{6 \div 3}{9 \div 3} = \frac{2}{3}$$

Math Review

Use Fractions

A fraction compares a part to a whole. In the fraction $\frac{2}{3}$, the 2 represents the part and is the numerator. The 3 represents the whole and is the denominator.

Reduce Fractions To reduce a fraction, you must find the largest factor that is common to both the numerator and the denominator, the greatest common factor (GCF). Divide both numbers by the GCF. The fraction has then been reduced, or it is in its simplest form.

Example Twelve of the 20 chemicals in the science lab are in powder form. What fraction of the chemicals used in the lab are in powder form?

Step 1 Write the fraction.

$$\frac{\text{part}}{\text{whole}} = \frac{12}{20}$$

Step 2 To find the GCF of the numerator and denominator, list all of the factors of each number.

Factors of 12: 1, 2, 3, 4, 6, 12 (the numbers that divide evenly into 12)

Factors of 20: 1, 2, 4, 5, 10, 20 (the numbers that divide evenly into 20)

Step 3 List the common factors.
1, 2, 4

Step 4 Choose the greatest factor in the list.
The GCF of 12 and 20 is 4.

Step 5 Divide the numerator and denominator by the GCF.

$$\frac{12 \div 4}{20 \div 4} = \frac{3}{5}$$

In the lab, $\frac{3}{5}$ of the chemicals are in powder form.

Practice Problem At an amusement park, 66 of 90 rides have a height restriction. What fraction of the rides, in its simplest form, has a height restriction?

Add and Subtract Fractions To add or subtract fractions with the same denominator, add or subtract the numerators and write the sum or difference over the denominator. After finding the sum or difference, find the simplest form for your fraction.

Example 1 In the forest outside your house, $\frac{1}{8}$ of the animals are rabbits, $\frac{3}{8}$ are squirrels, and the remainder are birds and insects. How many are mammals?

Step 1 Add the numerators.

$$\frac{1}{8} + \frac{3}{8} = \frac{(1+3)}{8} = \frac{4}{8}$$

Step 2 Find the GCF.

$$\frac{4}{8} \text{ (GCF, 4)}$$

Step 3 Divide the numerator and denominator by the GCF.

$$\frac{4 \div 4}{8 \div 4} = \frac{1}{2}$$

$\frac{1}{2}$ of the animals are mammals.

Example 2 If $\frac{7}{16}$ of the Earth is covered by freshwater, and $\frac{1}{16}$ of that is in glaciers, how much freshwater is not frozen?

Step 1 Subtract the numerators.

$$\frac{7}{16} - \frac{1}{16} = \frac{(7-1)}{16} = \frac{6}{16}$$

Step 2 Find the GCF.

$$\frac{6}{16} \text{ (GCF, 2)}$$

Step 3 Divide the numerator and denominator by the GCF.

$$\frac{6 \div 2}{16 \div 2} = \frac{3}{8}$$

$\frac{3}{8}$ of the freshwater is not frozen.

Practice Problem A bicycle rider is riding at a rate of 15 km/h for $\frac{4}{9}$ of his ride, 10 km/h for $\frac{2}{9}$ of his ride, and 8 km/h for the remainder of the ride. How much of his ride is he riding at a rate greater than 8 km/h?

Unlike Denominators To add or subtract fractions with unlike denominators, first find the least common denominator (LCD). This is the smallest number that is a common multiple of both denominators. Rename each fraction with the LCD, and then add or subtract. Find the simplest form if necessary.

Example 1 A chemist makes a paste that is $\frac{1}{2}$ table salt (NaCl), $\frac{1}{3}$ sugar ($C_6H_{12}O_6$), and the remainder is water (H_2O). How much of the paste is a solid?

Step 1 Find the LCD of the fractions.

$$\frac{1}{2} + \frac{1}{3} \quad (\text{LCD}, 6)$$

Step 2 Rename each numerator and each denominator with the LCD.

Step 3 Add the numerators.

$$\frac{3}{6} + \frac{2}{6} = \frac{(3 + 2)}{6} = \frac{5}{6}$$

$\frac{5}{6}$ of the paste is a solid.

Example 2 The average precipitation in Grand Junction, CO, is $\frac{7}{10}$ inch in November, and $\frac{3}{5}$ inch in December. What is the total average precipitation?

Step 1 Find the LCD of the fractions.

$$\frac{7}{10} + \frac{3}{5} \quad (\text{LCD}, 10)$$

Step 2 Rename each numerator and each denominator with the LCD.

Step 3 Add the numerators.

$$\frac{7}{10} + \frac{6}{10} = \frac{(7 + 6)}{10} = \frac{13}{10}$$

$\frac{13}{10}$ inches total precipitation, or $1\frac{3}{10}$ inches.

Practice Problem On an electric bill, about $\frac{1}{8}$ of the energy is from solar energy and about $\frac{1}{10}$ is from wind power. How much of the total bill is from solar energy and wind power combined?

Example 3 In your body, $\frac{7}{10}$ of your muscle contractions are involuntary (cardiac and smooth muscle tissue). Smooth muscle makes $\frac{3}{15}$ of your muscle contractions. How many of your muscle contractions are made by cardiac muscle?

Step 1 Find the LCD of the fractions.

$$\frac{7}{10} - \frac{3}{15} \quad (\text{LCD}, 30)$$

Step 2 Rename each numerator and each denominator with the LCD.

$$7 \times 3 = 21, \quad 10 \times 3 = 30$$

$$3 \times 2 = 6, \quad 15 \times 2 = 30$$

Step 3 Subtract the numerators.

$$\frac{21}{30} - \frac{6}{30} = \frac{(21 - 6)}{30} = \frac{15}{30}$$

Step 4 Find the GCF.

$$\frac{15}{30} \quad (\text{GCF}, 15)$$

$$\frac{1}{2}$$

$\frac{1}{2}$ of all muscle contractions are cardiac muscle.

Example 4 Tony wants to make cookies that call for $\frac{3}{4}$ of a cup of flour, but he only has $\frac{1}{3}$ of a cup. How much more flour does he need?

Step 1 Find the LCD of the fractions.

$$\frac{3}{4} - \frac{1}{3} \quad (\text{LCD}, 12)$$

Step 2 Rename each numerator and each denominator with the LCD.

$$\frac{3 \times 3}{4 \times 3} = \frac{9}{12}$$

$$\frac{1 \times 4}{3 \times 4} = \frac{4}{12}$$

Step 3 Subtract the numerators.

$$\frac{9}{12} - \frac{4}{12} = \frac{(9 - 4)}{12} = \frac{5}{12}$$

$\frac{5}{12}$ of a cup of flour

Practice Problem Using the information provided to you in Example 3 above, determine how many muscle contractions are voluntary (skeletal muscle).

Unlike Denominators

Problem 1

$$1 \times 5 = 5, 8 \times 5 = 40$$

$$1 \times 4 = 4, 10 \times 4 = 40$$

$$\frac{5}{40} + \frac{4}{40} = \frac{9}{40}$$

Problem 2

If $\frac{7}{10}$ are involuntary, the remainder are voluntary.

$$\frac{10}{40} - \frac{7}{10} = \frac{3}{40}$$

Multiply Fractions

$$\frac{3}{14} \times \frac{5}{16} = \frac{(3 \cdot 5)}{(14 \times 16)} = \frac{15}{224}$$

Find a Reciprocal

$$\frac{9}{4}$$

Divide Fractions

The reciprocal of $\frac{7}{10}$ is $\frac{10}{7}$.

$$\frac{3}{11} \times \frac{10}{7} = \frac{(3 \times 10)}{(11 \times 7)} = \frac{30}{77}$$

Math Skill Handbook

Multiply Fractions To multiply with fractions, multiply the numerators and multiply the denominators. Find the simplest form if necessary.

Example Multiply $\frac{3}{5}$ by $\frac{1}{3}$.

Step 1 Multiply the numerators and denominators.

$$\frac{3}{5} \times \frac{1}{3} = \frac{(3 \times 1)}{(5 \times 3)} = \frac{3}{15}$$

Step 2 Find the GCF.

$$\frac{3}{15} \text{ (GCF, 3)}$$

Step 3 Divide the numerator and denominator by the GCF.

$$\frac{3 \div 3}{15 \div 3} = \frac{1}{5}$$

$\frac{3}{5}$ multiplied by $\frac{1}{3}$ is $\frac{1}{5}$.

Practice Problem Multiply $\frac{3}{14}$ by $\frac{5}{16}$.

Find a Reciprocal Two numbers whose product is 1 are called multiplicative inverses, or reciprocals.

Example Find the reciprocal of $\frac{3}{8}$.

Step 1 Inverse the fraction by putting the denominator on top and the numerator on the bottom.

$$\frac{8}{3}$$

The reciprocal of $\frac{3}{8}$ is $\frac{8}{3}$.

Practice Problem Find the reciprocal of $\frac{4}{9}$.

Divide Fractions To divide one fraction by another fraction, multiply the dividend by the reciprocal of the divisor. Find the simplest form if necessary.

Example 1 Divide $\frac{1}{9}$ by $\frac{1}{3}$.

Step 1 Find the reciprocal of the divisor.

The reciprocal of $\frac{1}{3}$ is $\frac{3}{1}$.

Step 2 Multiply the dividend by the reciprocal of the divisor.

$$\frac{1}{9} \div \frac{1}{3} = \frac{1}{9} \times \frac{3}{1} = \frac{(1 \times 3)}{(9 \times 1)} = \frac{3}{9}$$

Step 3 Find the GCF.

$$\frac{3}{9} \text{ (GCF, 3)}$$

Step 4 Divide the numerator and denominator by the GCF.

$$\frac{3 \div 3}{9 \div 3} = \frac{1}{3}$$

$\frac{1}{9}$ divided by $\frac{1}{3}$ is $\frac{1}{3}$.

Example 2 Divide $\frac{3}{5}$ by $\frac{1}{4}$.

Step 1 Find the reciprocal of the divisor.

The reciprocal of $\frac{1}{4}$ is $\frac{4}{1}$.

Step 2 Multiply the dividend by the reciprocal of the divisor.

$$\frac{3}{5} \div \frac{1}{4} = \frac{3}{5} \times \frac{4}{1} = \frac{(3 \times 4)}{(5 \times 1)} = \frac{12}{5}$$

$\frac{3}{5}$ divided by $\frac{1}{4}$ is $\frac{12}{5}$ or $2\frac{2}{5}$.

Practice Problem Divide $\frac{3}{11}$ by $\frac{7}{10}$.

Use Ratios

$$\frac{100 \text{ cm}}{144 \text{ cm}} = \frac{100 \div 4}{144 \div 4} = \frac{25}{36}$$

25:36

Add or Subtract Decimals

$$\begin{array}{r} 1 \\ 1.245 \\ + 3.842 \\ \hline 5.087 \end{array}$$

Use Ratios

When you compare two numbers by division, you are using a ratio. Ratios can be written 3 to 5, 3:5, or $\frac{3}{5}$. Ratios, like fractions, also can be written in simplest form.

Ratios can represent one type of probability, called odds. This is a ratio that compares the number of ways a certain outcome occurs to the number of possible outcomes. For example, if you flip a coin 100 times, what are the odds that it will come up heads? There are two possible outcomes, heads or tails, so the odds of coming up heads are 50:100. Another way to say this is that 50 out of 100 times the coin will come up heads. In its simplest form, the ratio is 1:2.

Example 1 A chemical solution contains 40 g of salt and 64 g of baking soda. What is the ratio of salt to baking soda as a fraction in simplest form?

Step 1 Write the ratio as a fraction.

$$\frac{\text{salt}}{\text{baking soda}} = \frac{40}{64}$$

Step 2 Express the fraction in simplest form.

The GCF of 40 and 64 is 8.

$$\frac{40}{64} = \frac{40 \div 8}{64 \div 8} = \frac{5}{8}$$

The ratio of salt to baking soda in the sample is 5:8.

Example 2 Sean rolls a 6-sided die 6 times. What are the odds that the side with a 3 will show?

Step 1 Write the ratio as a fraction.

$$\frac{\text{number of sides with a 3}}{\text{number of possible sides}} = \frac{1}{6}$$

Step 2 Multiply by the number of attempts.

$$\frac{1}{6} \times 6 \text{ attempts} = \frac{6}{6} \text{ attempts} = 1 \text{ attempt}$$

1 attempt out of 6 will show a 3.

Practice Problem Two metal rods measure 100 cm and 144 cm in length. What is the ratio of their lengths in simplest form?

Use Decimals

A fraction with a denominator that is a power of ten can be written as a decimal. For example, 0.27 means $\frac{27}{100}$. The decimal point separates the ones place from the tenths place.

Any fraction can be written as a decimal using division. For example, the fraction $\frac{5}{8}$ can be written as a decimal by dividing 5 by 8. Written as a decimal, it is 0.625.

Add or Subtract Decimals When adding and subtracting decimals, line up the decimal points before carrying out the operation.

Example 1 Find the sum of 47.68 and 7.80.

Step 1 Line up the decimal places when you write the numbers.

$$\begin{array}{r} 47.68 \\ + 7.80 \\ \hline \end{array}$$

Step 2 Add the decimals.

$$\begin{array}{r} 11 \\ 47.68 \\ + 7.80 \\ \hline 55.48 \end{array}$$

The sum of 47.68 and 7.80 is 55.48.

Example 2 Find the difference of 42.17 and 15.85.

Step 1 Line up the decimal places when you write the number.

$$\begin{array}{r} 42.17 \\ - 15.85 \\ \hline \end{array}$$

Step 2 Subtract the decimals.

$$\begin{array}{r} 3111 \\ 42.17 \\ - 15.85 \\ \hline 26.32 \end{array}$$

The difference of 42.17 and 15.85 is 26.32.

Practice Problem Find the sum of 1.245 and 3.842.

Multiply Decimals

Multiply 4.6 and 2.2 by 10.

$$46 \times 22 = 1012$$

Each factor had one decimal place.

$$10.12$$

Divide Decimals

Multiply both factors by 10.

Divide 756 by 36.

$$\begin{array}{r} 21 \\ 36 \overline{)756} \\ \underline{72} \\ 36 \\ \underline{36} \\ 0 \end{array}$$

Use Proportions

$$\frac{3}{18} = \frac{5}{w}$$

$$w \times 3 = 5 \times 18$$

$$\frac{3w}{3} = \frac{90}{3}$$

$$w = 30$$

Math Skill Handbook

Multiply Decimals To multiply decimals, multiply the numbers like you multiply numbers without decimals. Count the decimal places in each factor. The product will have the same number of decimal places as the sum of the decimal places in the factors.

Example Multiply 2.4 by 5.9.

Step 1 Multiply the factors like two whole numbers.

$$24 \times 59 = 1416$$

Step 2 Find the sum of the number of decimal places in the factors. Each factor has one decimal place, for a sum of two decimal places.

Step 3 The product will have two decimal places.
14.16

The product of 2.4 and 5.9 is 14.16.

Practice Problem Multiply 4.6 by 2.2.

Divide Decimals When dividing decimals, change the divisor to a whole number. To do this, multiply both the divisor and the dividend by the same power of ten. Then place the decimal point in the quotient directly above the decimal point in the dividend. Then divide as you do with whole numbers.

Example Divide 8.84 by 3.4.

Step 1 Multiply both factors by 10.

$$3.4 \times 10 = 34, 8.84 \times 10 = 88.4$$

Step 2 Divide 88.4 by 34.

$$\begin{array}{r} 2.6 \\ 34 \overline{)88.4} \\ \underline{-68} \\ 204 \\ \underline{-204} \\ 0 \end{array}$$

8.84 divided by 3.4 is 2.6.

Practice Problem Divide 75.6 by 3.6.

Use Proportions

An equation that shows that two ratios are equivalent is a proportion. The ratios $\frac{2}{4}$ and $\frac{5}{10}$ are equivalent, so they can be written as $\frac{2}{4} = \frac{5}{10}$. This equation is a proportion.

When two ratios form a proportion, the cross products are equal. To find the cross products in the proportion $\frac{2}{4} = \frac{5}{10}$, multiply the 2 and the 10, and the 4 and the 5. Therefore $2 \times 10 = 4 \times 5$, or $20 = 20$.

Because you know that both ratios are equal, you can use cross products to find a missing term in a proportion. This is known as solving the proportion.

Example The heights of a tree and a pole are proportional to the lengths of their shadows. The tree casts a shadow of 24 m when a 6-m pole casts a shadow of 4 m. What is the height of the tree?

Step 1 Write a proportion.

$$\frac{\text{height of tree}}{\text{height of pole}} = \frac{\text{length of tree's shadow}}{\text{length of pole's shadow}}$$

Step 2 Substitute the known values into the proportion. Let h represent the unknown value, the height of the tree.

$$\frac{h}{6} = \frac{24}{4}$$

Step 3 Find the cross products.

$$h \times 4 = 6 \times 24$$

Step 4 Simplify the equation.

$$4h = 144$$

Step 5 Divide each side by 4.

$$\frac{4h}{4} = \frac{144}{4}$$
$$h = 36$$

The height of the tree is 36 m.

Practice Problem The ratios of the weights of two objects on the Moon and on Earth are in proportion. A rock weighing 3 N on the Moon weighs 18 N on Earth. How much would a rock that weighs 5 N on the Moon weigh on Earth?

Use Percentages

The word *percent* means “out of one hundred.” It is a ratio that compares a number to 100. Suppose you read that 77 percent of the Earth’s surface is covered by water. That is the same as reading that the fraction of the Earth’s surface covered by water is $\frac{77}{100}$. To express a fraction as a percent, first find the equivalent decimal for the fraction. Then, multiply the decimal by 100 and add the percent symbol.

Example Express $\frac{13}{20}$ as a percent.

Step 1 Find the equivalent decimal for the fraction.

$$\begin{array}{r} 0.65 \\ 20 \overline{)13.00} \\ \underline{12\ 0} \\ 1\ 00 \\ \underline{1\ 00} \\ 0 \end{array}$$

Step 2 Rewrite the fraction $\frac{13}{20}$ as 0.65.

Step 3 Multiply 0.65 by 100 and add the % symbol.
 $0.65 \times 100 = 65 = 65\%$

So, $\frac{13}{20} = 65\%$.

This also can be solved as a proportion.

Example Express $\frac{13}{20}$ as a percent.

Step 1 Write a proportion.

$$\frac{13}{20} = \frac{x}{100}$$

Step 2 Find the cross products.

$$1300 = 20x$$

Step 3 Divide each side by 20.

$$\begin{array}{r} 1300 = 20x \\ \underline{20} \quad \underline{20} \\ 65\% = x \end{array}$$

Practice Problem In one year, 73 of 365 days were rainy in one city. What percent of the days in that city were rainy?

Solve One-Step Equations

A statement that two expressions are equal is an equation. For example, $A = B$ is an equation that states that A is equal to B .

An equation is solved when a variable is replaced with a value that makes both sides of the equation equal. To make both sides equal the inverse operation is used. Addition and subtraction are inverses, and multiplication and division are inverses.

Example 1 Solve the equation $x - 10 = 35$.

Step 1 Find the solution by adding 10 to each side of the equation.

$$\begin{aligned} x - 10 &= 35 \\ x - 10 + 10 &= 35 + 10 \\ x &= 45 \end{aligned}$$

Step 2 Check the solution.

$$\begin{aligned} x - 10 &= 35 \\ 45 - 10 &= 35 \\ 35 &= 35 \end{aligned}$$

Both sides of the equation are equal, so $x = 45$.

Example 2 In the formula $a = bc$, find the value of c if $a = 20$ and $b = 2$.

Step 1 Rearrange the formula so the unknown value is by itself on one side of the equation by dividing both sides by b .

$$\begin{aligned} a &= bc \\ \frac{a}{b} &= \frac{bc}{b} \\ \frac{a}{b} &= c \end{aligned}$$

Step 2 Replace the variables a and b with the values that are given.

$$\begin{aligned} \frac{a}{b} &= c \\ \frac{20}{2} &= c \\ 10 &= c \end{aligned}$$

Step 3 Check the solution.

$$\begin{aligned} a &= bc \\ 20 &= 2 \times 10 \\ 20 &= 20 \end{aligned}$$

Both sides of the equation are equal, so $c = 10$ is the solution when $a = 20$ and $b = 2$.

Practice Problem In the formula $h = gd$, find the value of d if $g = 12.3$ and $h = 17.4$.

Use Percentages

$$\begin{aligned} \frac{73}{365} &= \frac{x}{100} \\ \frac{7300}{365} &= \frac{365x}{365} \\ 20\% &= x \end{aligned}$$

Solve One-Step Equations

$$h = gd$$

$$\frac{17.4}{12.3} = \frac{12.3d}{12.3}$$

$$1.41 \approx d$$

Use Statistics

mean

$$8 + 4 + 12 + 8 + 11 + 14 + 16 = 73$$

$$73 \div 7 \approx 10.4$$

median

4, 8, 8, 11, 12, 14, 16

mode

4, 8, 8, 11, 12, 14, 16

range

4, 8, 8, 11, 12, 14, 16

$$16 - 4 = 12$$

Text Question

Answer

purple

Math Skill Handbook

Use Statistics

The branch of mathematics that deals with collecting, analyzing, and presenting data is statistics. In statistics, there are three common ways to summarize data with a single number—the mean, the median, and the mode.

The **mean** of a set of data is the arithmetic average. It is found by adding the numbers in the data set and dividing by the number of items in the set.

The **median** is the middle number in a set of data when the data are arranged in numerical order. If there were an even number of data points, the median would be the mean of the two middle numbers.

The **mode** of a set of data is the number or item that appears most often.

Another number that often is used to describe a set of data is the range. The **range** is the difference between the largest number and the smallest number in a set of data.

A **frequency table** shows how many times each piece of data occurs, usually in a survey. **Table 2** below shows the results of a student survey on favorite color.

Table 2 Student Color Choice

Color	Tally	Frequency
Red		4
Blue		5
Black		2
Green		3
Purple		7
Yellow		6

Based on the frequency table data, which color is the favorite?

Example The speeds (in m/s) for a race car during five different time trials are 39, 37, 44, 36, and 44.

To find the mean:

Step 1 Find the sum of the numbers.

$$39 + 37 + 44 + 36 + 44 = 200$$

Step 2 Divide the sum by the number of items, which is 5.

$$200 \div 5 = 40$$

The mean is 40 m/s.

To find the median:

Step 1 Arrange the measures from least to greatest.

36, 37, 39, 44, 44

Step 2 Determine the middle measure.

36, 37, 39, 44, 44

The median is 39 m/s.

To find the mode:

Step 1 Group the numbers that are the same together.

44, 44, 36, 37, 39

Step 2 Determine the number that occurs most in the set.

44, 44, 36, 37, 39

The mode is 44 m/s.

To find the range:

Step 1 Arrange the measures from greatest to least.

44, 44, 39, 37, 36

Step 2 Determine the greatest and least measures in the set.

44, 44, 39, 37, 36

Step 3 Find the difference between the greatest and least measures.

$$44 - 36 = 8$$

The range is 8 m/s.

Practice Problem Find the mean, median, mode, and range for the data set 8, 4, 12, 8, 11, 14, 16.

Use Geometry

The branch of mathematics that deals with the measurement, properties, and relationships of points, lines, angles, surfaces, and solids is called geometry.

Perimeter The **perimeter** (P) is the distance around a geometric figure. To find the perimeter of a rectangle, add the length and width and multiply that sum by two, or $2(l + w)$. To find perimeters of irregular figures, add the length of the sides.

Example 1 Find the perimeter of a rectangle that is 3 m long and 5 m wide.

Step 1 You know that the perimeter is 2 times the sum of the width and length.
 $P = 2(3 \text{ m} + 5 \text{ m})$

Step 2 Find the sum of the width and length.
 $P = 2(8 \text{ m})$

Step 3 Multiply by 2.
 $P = 16 \text{ m}$

The perimeter is 16 m.

Example 2 Find the perimeter of a shape with sides measuring 2 cm, 5 cm, 6 cm, 3 cm.

Step 1 You know that the perimeter is the sum of all the sides.
 $P = 2 + 5 + 6 + 3$

Step 2 Find the sum of the sides.
 $P = 2 + 5 + 6 + 3$
 $P = 16$

The perimeter is 16 cm.

Practice Problem Find the perimeter of a rectangle with a length of 18 m and a width of 7 m.

Practice Problem Find the perimeter of a triangle measuring 1.6 cm by 2.4 cm by 2.4 cm.

Area of a Rectangle The **area** (A) is the number of square units needed to cover a surface. To find the area of a rectangle, multiply the length times the width, or $l \times w$. When finding area, the units also are multiplied. Area is given in square units.

Example Find the area of a rectangle with a length of 1 cm and a width of 10 cm.

Step 1 You know that the area is the length multiplied by the width.
 $A = (1 \text{ cm} \times 10 \text{ cm})$

Step 2 Multiply the length by the width. Also multiply the units.
 $A = 10 \text{ cm}^2$

The area is 10 cm^2 .

Practice Problem Find the area of a square whose sides measure 4 m.

Area of a Triangle To find the area of a triangle, use the formula:

$$A = \frac{1}{2}(\text{base} \times \text{height})$$

The base of a triangle can be any of its sides. The height is the perpendicular distance from a base to the opposite endpoint, or vertex.

Example Find the area of a triangle with a base of 18 m and a height of 7 m.

Step 1 You know that the area is $\frac{1}{2}$ the base times the height.
 $A = \frac{1}{2}(18 \text{ m} \times 7 \text{ m})$

Step 2 Multiply $\frac{1}{2}$ by the product of 18×7 . Multiply the units.
 $A = \frac{1}{2}(126 \text{ m}^2)$
 $A = 63 \text{ m}^2$

The area is 63 m^2 .

Practice Problem Find the area of a triangle with a base of 27 cm and a height of 17 cm.

Perimeter

Problem 1

$$P = 2(18 \text{ m} + 7 \text{ m})$$

$$P = 2(25 \text{ m})$$

$$P = 50 \text{ m}$$

Problem 2

$$P = 1.6 \text{ cm} + 2.4 \text{ cm} + 2.4 \text{ cm}$$

$$P = 6.4 \text{ cm}$$

Area of a Rectangle

$$A = (4 \text{ m} \times 4 \text{ m})$$

$$A = 16 \text{ m}^2$$

Area of a Triangle

$$A = \frac{1}{2}(27 \text{ cm} \times 17 \text{ cm})$$

$$A = \frac{1}{2}(459 \text{ cm}^2)$$

$$A = 229.5 \text{ cm}^2$$

Circumference of a Circle

$$C = 2\pi r$$
$$C = 2\pi(19)$$
$$C = 38\pi$$
$$C \approx 119.4$$

Area of a Circle

$$A = \pi r^2$$
$$A = \pi(16\text{ m})^2$$
$$A = \pi 256\text{ m}^2$$
$$A \approx 804.2\text{ m}^2$$

Math Skill Handbook

Circumference of a Circle The diameter (d) of a circle is the distance across the circle through its center, and the **radius** (r) is the distance from the center to any point on the circle. The radius is half of the diameter. The distance around the circle is called the **circumference** (C). The formula for finding the circumference is:

$$C = 2\pi r \text{ or } C = \pi d$$

The circumference divided by the diameter is always equal to 3.1415926... This nonterminating and nonrepeating number is represented by the Greek letter π (pi). An approximation often used for π is 3.14.

Example 1 Find the circumference of a circle with a radius of 3 m.

Step 1 You know the formula for the circumference is 2 times the radius times π .
 $C = 2\pi(3)$

Step 2 Multiply 2 times the radius.
 $C = 6\pi$

Step 3 Multiply by π .
 $C = 19\text{ m}$

The circumference is 19 m.

Example 2 Find the circumference of a circle with a diameter of 24.0 cm.

Step 1 You know the formula for the circumference is the diameter times π .
 $C = \pi(24.0)$

Step 2 Multiply the diameter by π .
 $C = 75.4\text{ cm}$

The circumference is 75.4 cm.

Practice Problem Find the circumference of a circle with a radius of 19 cm.

Area of a Circle The formula for the area of a circle is:

$$A = \pi r^2$$

Example 1 Find the area of a circle with a radius of 4.0 cm.

Step 1 $A = \pi(4.0)^2$

Step 2 Find the square of the radius.
 $A = 16\pi$

Step 3 Multiply the square of the radius by π .
 $A = 50\text{ cm}^2$

The area of the circle is 50 cm².

Example 2 Find the area of a circle with a radius of 225 m.

Step 1 $A = \pi(225)^2$

Step 2 Find the square of the radius.
 $A = 50625\pi$

Step 3 Multiply the square of the radius by π .
 $A = 158962.5$

The area of the circle is 158,962 m².

Example 3 Find the area of a circle whose diameter is 20.0 mm.

Step 1 You know the formula for the area of a circle is the square of the radius times π , and that the radius is half of the diameter.
 $A = \pi\left(\frac{20.0}{2}\right)^2$

Step 2 Find the radius.
 $A = \pi(10.0)^2$

Step 3 Find the square of the radius.
 $A = 100\pi$

Step 4 Multiply the square of the radius by π .
 $A = 314\text{ mm}^2$

The area is 314 mm².

Practice Problem Find the area of a circle with a radius of 16 m.

Volume The measure of space occupied by a solid is the **volume** (V). To find the volume of a rectangular solid multiply the length times width times height, or $V = l \times w \times h$. It is measured in cubic units, such as cubic centimeters (cm^3).

Example Find the volume of a rectangular solid with a length of 2.0 m, a width of 4.0 m, and a height of 3.0 m.

Step 1 You know the formula for volume is the length times the width times the height.
 $V = 2.0 \text{ m} \times 4.0 \text{ m} \times 3.0 \text{ m}$

Step 2 Multiply the length times the width times the height.
 $V = 24 \text{ m}^3$

The volume is 24 m^3 .

Practice Problem Find the volume of a rectangular solid that is 8 m long, 4 m wide, and 4 m high.

To find the volume of other solids, multiply the area of the base times the height.

Example 1 Find the volume of a solid that has a triangular base with a length of 8.0 m and a height of 7.0 m. The height of the entire solid is 15.0 m.

Step 1 You know that the base is a triangle, and the area of a triangle is $\frac{1}{2}$ the base times the height, and the volume is the area of the base times the height.
 $V = \frac{1}{2} (b \cdot h) \cdot 15$

Step 2 Find the area of the base.
 $V = \left[\frac{1}{2} (8 \times 7) \right] \times 15$
 $V = \left(\frac{1}{2} \times 56 \right) \times 15$

Step 3 Multiply the area of the base by the height of the solid.
 $V = 28 \times 15$
 $V = 420 \text{ m}^3$

The volume is 420 m^3 .

Example 2 Find the volume of a cylinder that has a base with a radius of 12.0 cm, and a height of 21.0 cm.

Step 1 You know that the base is a circle, and the area of a circle is the square of the radius times π , and the volume is the area of the base times the height.
 $V = (\pi r^2) \times 21$
 $V = (\pi 12^2) \times 21$

Step 2 Find the area of the base.
 $V = 144\pi \times 21$
 $V = 452 \times 21$

Step 3 Multiply the area of the base by the height of the solid.
 $V = 9,490 \text{ cm}^3$

The volume is $9,500 \text{ cm}^3$.

Example 3 Find the volume of a cylinder that has a diameter of 15 mm and a height of 4.8 mm.

Step 1 You know that the base is a circle with an area equal to the square of the radius times π . The radius is one-half the diameter. The volume is the area of the base times the height.
 $V = (\pi r^2) \times 4.8$
 $V = \left[\pi \left(\frac{1}{2} \times 15 \right)^2 \right] \times 4.8$
 $V = (\pi 7.5^2) \times 4.8$

Step 2 Find the area of the base.
 $V = 56.25\pi \times 4.8$
 $V \approx 176.63 \times 4.8$

Step 3 Multiply the area of the base by the height of the solid.
 $V = 847.8$

The volume is 847.8 mm^3 .

Practice Problem Find the volume of a cylinder with a diameter of 7 cm in the base and a height of 16 cm.

Volume

Problem 1

$$V = 8 \text{ m} \times 4 \text{ m} \times 4 \text{ m}$$

$$V = 128 \text{ m}^3$$

Problem 2

$$V = \pi r^2 \times \text{height}$$

$$V = \left[\pi \left(\frac{1}{2} \times 7 \right)^2 \right] \times 16$$

$$V = [\pi(3.5)^2] \times 16$$

$$V = [\pi(12.25)] \times 16$$

$$V \approx 38.48 \times 16$$

$$V \approx 615.75$$

Measure in SI

smaller; 1000; one thousandth

Dimensional Analysis

$$x \text{ mg} = 1 \text{ kg} \times \frac{1000 \text{ g}}{1 \text{ kg}} \times \frac{1000 \text{ mg}}{1 \text{ g}} =$$

$$1,000,000 \text{ mg}$$

$$1,000,000 \text{ mg} = 1 \text{ kg}$$

Math Skill Handbook

Science Applications

Measure in SI

The metric system of measurement was developed in 1795. A modern form of the metric system, called the International System (SI), was adopted in 1960 and provides the standard measurements that all scientists around the world can understand.

The SI system is convenient because unit sizes vary by powers of 10. Prefixes are used to name units. Look at **Table 3** for some common SI prefixes and their meanings.

Table 3 Common SI Prefixes

Prefix	Symbol	Meaning	
kilo-	k	1,000	thousand
hecto-	h	100	hundred
deka-	da	10	ten
deci-	d	0.1	tenth
centi-	c	0.01	hundredth
milli-	m	0.001	thousandth

Example How many grams equal one kilogram?

Step 1 Find the prefix *kilo-* in **Table 3**.

Step 2 Using **Table 3**, determine the meaning of *kilo-*. According to the table, it means 1,000. When the prefix *kilo-* is added to a unit, it means that there are 1,000 of the units in a "kilounit."

Step 3 Apply the prefix to the units in the question. The units in the question are grams. There are 1,000 grams in a kilogram.

Practice Problem Is a milligram larger or smaller than a gram? How many of the smaller units equal one larger unit? What fraction of the larger unit does one smaller unit represent?

Dimensional Analysis

Convert SI Units In science, quantities such as length, mass, and time sometimes are measured using different units. A process called dimensional analysis can be used to change one unit of measure to another. This process involves multiplying your starting quantity and units by one or more conversion factors. A conversion factor is a ratio equal to one and can be made from any two equal quantities with different units. If 1,000 mL equal 1 L then two ratios can be made.

$$\frac{1,000 \text{ mL}}{1 \text{ L}} = \frac{1 \text{ L}}{1,000 \text{ mL}} = 1$$

One can convert between units in the SI system by using the equivalents in **Table 3** to make conversion factors.

Example 1 How many cm are in 4 m?

Step 1 Write conversion factors for the units given. From **Table 3**, you know that $100 \text{ cm} = 1 \text{ m}$. The conversion factors are

$$\frac{100 \text{ cm}}{1 \text{ m}} \text{ and } \frac{1 \text{ m}}{100 \text{ cm}}$$

Step 2 Decide which conversion factor to use. Select the factor that has the units you are converting from (m) in the denominator and the units you are converting to (cm) in the numerator.

$$\frac{100 \text{ cm}}{1 \text{ m}}$$

Step 3 Multiply the starting quantity and units by the conversion factor. Cancel the starting units with the units in the denominator. There are 400 cm in 4 m.

$$4 \text{ m} \times \frac{100 \text{ cm}}{1 \text{ m}} = 400 \text{ cm}$$

Practice Problem How many milligrams are in one kilogram? (Hint: You will need to use two conversion factors from **Table 3**.)

Table 4 Unit System Equivalents

Type of Measurement	Equivalent
Length	1 in = 2.54 cm 1 yd = 0.91 m 1 mi = 1.61 km
Mass and weight*	1 oz = 28.35 g 1 lb = 0.45 kg 1 ton (short) = 0.91 tonnes (metric tons) 1 lb = 4.45 N
Volume	1 in ³ = 16.39 cm ³ 1 qt = 0.95 L 1 gal = 3.78 L
Area	1 in ² = 6.45 cm ² 1 yd ² = 0.83 m ² 1 mi ² = 2.59 km ² 1 acre = 0.40 hectares
Temperature	°C = $\frac{°F - 32}{1.8}$ K = C + 273

*Weight is measured in standard Earth gravity.

Convert Between Unit Systems Table 4 gives a list of equivalents that can be used to convert between English and SI units.

Example If a meterstick has a length of 100 cm, how long is the meterstick in inches?

Step 1 Write the conversion factors for the units given. From Table 4, 1 in = 2.54 cm.

$$\frac{1 \text{ in}}{2.54 \text{ cm}} \text{ and } \frac{2.54 \text{ cm}}{1 \text{ in}}$$

Step 2 Determine which conversion factor to use. You are converting from cm to in. Use the conversion factor with cm on the bottom.

$$\frac{1 \text{ in}}{2.54 \text{ cm}}$$

Step 3 Multiply the starting quantity and units by the conversion factor. Cancel the starting units with the units in the denominator. Round your answer to the nearest tenth.

$$100 \text{ cm} \times \frac{1 \text{ in}}{2.54 \text{ cm}} = 39.37 \text{ in}$$

The meterstick is about 39.4 in long.

Practice Problem A book has a mass of 5 lbs. What is the mass of the book in kg?

Practice Problem Use the equivalent for in and cm (1 in = 2.54 cm) to show how 1 in³ = 16.39 cm³.

Convert Between Unit Systems

Problem 1

$$5.45 \times \frac{0.45 \text{ kg}}{1 \text{ lb}} = 2.25 \text{ kg}$$

Problem 2

$$\begin{aligned} & \frac{(1 \text{ in})^3}{(2.54 \text{ cm})^3} \\ &= \frac{1 \text{ in} \times 1 \text{ in} \times 1 \text{ in}}{2.54 \text{ cm} \times 2.54 \text{ cm} \times 2.54 \text{ cm}} \\ &= \frac{1 \text{ in}^3}{16.39 \text{ cm}^3} \end{aligned}$$

Precision and Significant Digits

Problem 1

7; 4

Problem 2

$$5.28 \times 5.2 = 27.456$$

5.28 has 3 significant digits.

5.2 has 2 significant digits.

When multiplying and dividing, the answer is rounded to the smallest number of significant digits of the numbers being multiplied or divided—in this case, 2.

27.456 is rounded to 27.

Scientific Notation

Problem 1

4; 4

Problem 2

0.000007

Problem 3

$$5.39 \times 10^2$$

Math Skill Handbook

Precision and Significant Digits

When you make a measurement, the value you record depends on the precision of the measuring instrument. This precision is represented by the number of significant digits recorded in the measurement. When counting the number of significant digits, all digits are counted except zeros at the end of a number with no decimal point such as 2,050, and zeros at the beginning of a decimal such as 0.03020. When adding or subtracting numbers with different precision, round the answer to the smallest number of decimal places of any number in the sum or difference. When multiplying or dividing, the answer is rounded to the smallest number of significant digits of any number being multiplied or divided.

Example The lengths 5.28 and 5.2 are measured in meters. Find the sum of these lengths and record your answer using the correct number of significant digits.

Step 1 Find the sum.

$$\begin{array}{r} 5.28 \text{ m} \quad 2 \text{ digits after the decimal} \\ + 5.2 \text{ m} \quad 1 \text{ digit after the decimal} \\ \hline 10.48 \text{ m} \end{array}$$

Step 2 Round to one digit after the decimal because the least number of digits after the decimal of the numbers being added is 1.

The sum is 10.5 m.

Practice Problem How many significant digits are in the measurement 7,071,301 m? How many significant digits are in the measurement 0.003010 g?

Practice Problem Multiply 5.28 and 5.2 using the rule for multiplying and dividing. Record the answer using the correct number of significant digits.

Scientific Notation

Many times numbers used in science are very small or very large. Because these numbers are difficult to work with, scientists use scientific notation. To write numbers in scientific notation, move the decimal point until only one non-zero digit remains on the left. Then count the number of places you moved the decimal point and use that number as a power of ten. For example, the average distance from the Sun to Mars is 227,800,000,000 m. In scientific notation, this distance is 2.278×10^{11} m. Because you moved the decimal point to the left, the number is a positive power of ten.

The mass of an electron is about 0.000 000 000 000 000 000 000 000 911 kg. Expressed in scientific notation, this mass is 9.11×10^{-31} kg. Because the decimal point was moved to the right, the number is a negative power of ten.

Example Earth is 149,600,000 km from the Sun. Express this in scientific notation.

Step 1 Move the decimal point until one non-zero digit remains on the left.
1.496 000 00

Step 2 Count the number of decimal places you have moved. In this case, eight.

Step 3 Show that number as a power of ten, 10^8 .
Earth is 1.496×10^8 km from the Sun.

Practice Problem How many significant digits are in 149,600,000 km? How many significant digits are in 1.496×10^8 km?

Practice Problem Parts used in a high performance car must be measured to 7×10^{-6} m. Express this number as a decimal.

Practice Problem A CD is spinning at 539 revolutions per minute. Express this number in scientific notation.

12	86

Puppy Growth

Make and Use Graphs

Data in tables can be displayed in a graph—a visual representation of data. Common graph types include line graphs, bar graphs, and circle graphs.

Line Graph A line graph shows a relationship between two variables that change continuously. The independent variable is changed and is plotted on the x -axis. The dependent variable is observed, and is plotted on the y -axis.

Example Draw a line graph of the data below from a cyclist in a long-distance race.

Table 5 Bicycle Race Data	
Time (h)	Distance (km)
0	0
1	8
2	16
3	24
4	32
5	40

Figure 20 This line graph shows the relationship between distance and time during a bicycle ride.

Practice Problem A puppy's shoulder height is measured during the first year of her life. The following measurements were collected: (3 mo, 52 cm), (6 mo, 72 cm), (9 mo, 83 cm), (12 mo, 86 cm). Graph this data.

Find a Slope The slope of a straight line is the ratio of the vertical change, rise, to the horizontal change, run.

$$\text{Slope} = \frac{\text{vertical change (rise)}}{\text{horizontal change (run)}} = \frac{\text{change in } y}{\text{change in } x}$$

Example Find the slope of the graph in Figure 20.

Step 1 You know that the slope is the change in y divided by the change in x .

$$\text{Slope} = \frac{\text{change in } y}{\text{change in } x}$$

Step 2 Determine the data points you will be using.

For a straight line, choose the two sets of points that are the farthest apart.

$$\text{Slope} = \frac{(40-0) \text{ km}}{(5-0) \text{ h}}$$

Step 3 Find the change in y and x .

$$\text{Slope} = \frac{40 \text{ km}}{5 \text{ h}}$$

Step 4 Divide the change in y by the change in x .

$$\text{Slope} = \frac{8 \text{ km}}{\text{h}}$$

The slope of the graph is 8 km/h.

Bar Graph

Composition of Air

Circle Graph

The total amount of aluminum collected is:

$$4.0 \text{ kg} + 1.0 \text{ kg} + 2.0 \text{ kg} = 7.0 \text{ kg}$$

$$\frac{4.0 \text{ kg}}{7.0 \text{ kg}} = \frac{x}{360^\circ}; x = 206^\circ$$

$$\frac{1.0 \text{ kg}}{7.0 \text{ kg}} = \frac{x}{360^\circ}; x = 51^\circ$$

$$\frac{2.0 \text{ kg}}{7.0 \text{ kg}} = \frac{x}{360^\circ}; x = 103^\circ$$

Monday is 57% of graph, Wednesday is 14% of graph, and Friday is 29% of graph.

Math Skill Handbook

Bar Graph To compare data that does not change continuously you might choose a bar graph. A bar graph uses bars to show the relationships between variables. The x -axis variable is divided into parts. The parts can be numbers such as years, or a category such as a type of animal. The y -axis is a number and increases continuously along the axis.

Example A recycling center collects 4.0 kg of aluminum on Monday, 1.0 kg on Wednesday, and 2.0 kg on Friday. Create a bar graph of this data.

Step 1 Select the x -axis and y -axis variables. The measured numbers (the masses of aluminum) should be placed on the y -axis. The variable divided into parts (collection days) is placed on the x -axis.

Step 2 Create a graph grid like you would for a line graph. Include labels and units.

Step 3 For each measured number, draw a vertical bar above the x -axis value up to the y -axis value. For the first data point, draw a vertical bar above Monday up to 4.0 kg.

Aluminum Collected During Week

Practice Problem Draw a bar graph of the gases in air: 78% nitrogen, 21% oxygen, 1% other gases.

Circle Graph To display data as parts of a whole, you might use a circle graph. A circle graph is a circle divided into sections that represent the relative size of each piece of data. The entire circle represents 100%, half represents 50%, and so on.

Example Air is made up of 78% nitrogen, 21% oxygen, and 1% other gases. Display the composition of air in a circle graph.

Step 1 Multiply each percent by 360° and divide by 100 to find the angle of each section in the circle.

$$78\% \times \frac{360^\circ}{100} = 280.8^\circ$$

$$21\% \times \frac{360^\circ}{100} = 75.6^\circ$$

$$1\% \times \frac{360^\circ}{100} = 3.6^\circ$$

Step 2 Use a compass to draw a circle and to mark the center of the circle. Draw a straight line from the center to the edge of the circle.

Step 3 Use a protractor and the angles you calculated to divide the circle into parts. Place the center of the protractor over the center of the circle and line the base of the protractor over the straight line.

Practice Problem Draw a circle graph to represent the amount of aluminum collected during the week shown in the bar graph to the left.

EXTRA Math Problems

For help and hints with these problems, visit Math Practice at gpscience.com.

Chapter 1 The Nature of Science

- How many centimeters are in four meters?
- How many deciliters are in 500 mL?
- How many liters are in 2540 cm³?
- A young child has a mass of 40 kg. What is the mass of the child in grams?
- Iron has a density of 7.9 g/cm³. What is the mass in kg of an iron statue that has a volume of 5.4 L?
- A 2-L bottle of soda has a volume of 2000 cm³. What is the volume of the bottle in cubic meters?
- A big summer movie has a running time of 96 minutes. What is the movie's running time in seconds?
- The temperature in space is approximately 3 K. What is this temperature in degrees Celsius?
- The x-axis of a certain graph is distance traveled in meters and the y-axis is time in seconds. Two points are plotted on this graph with coordinates (2, 43) and (5, 68). What is the elapsed time between the two points?
- A circle graph has labeled segments of: 57%, 21%, 13%, and 6%. What percentage does the unlabeled segment have?

Chapter 2 Science, Technology, and Society

- A car can travel 14 km on 1 L of gasoline. What percentage of its fuel efficiency does another car have if it travels 10 km on 1 L of gasoline?
- What is the fuel efficiency of a car if it gets 45 percent of the fuel efficiency of another car that travels 15 km on 1 L of gasoline?
- If new information technology causes a three percent reduction in the 40,000,000 HIV infections worldwide, how many people would be infected?

- A circle graph shows the comparative effects of five new technologies. The circle graph has segments labeled 45 percent, 32 percent, 12 percent, and 3 percent. What is the correct label of the fifth segment?
- Data from a new Web site takes 17 min to download. How many seconds does it take?
- If a new internet connection reduces a download time of 17 min by 85 percent, how much time (in minutes and seconds) will it take now?
- Because of a new health center in a town, the cases of influenza are 25 percent fewer. If the town usually has 300 cases per month, how many cases should you expect during the next month?
- If a person can sell 10 computers per day and a new technology allows her to triple her sales, how many computers can she expect to sell the next day?
- If it normally takes 45 min to travel to a nearby town using an older train, but a new technologically advanced train can make the trip in one-third of the time, how long will the trip take?
- A technologically advanced engine runs at twice the efficiency of an older engine. If the older engine allows a car to travel at a fuel efficiency of 8 km/L, what is the fuel efficiency of the advanced engine?

Chapter 3 Motion, Acceleration, and Forces

- John rides his bike 2.3 km to school. After school, he rides an additional 1.4 km to the mall in the opposite direction. What is his total distance traveled?
- A squirrel runs 4.8 m across a lawn, stops, then runs 2.3 m back in the opposite direction. What is the squirrel's displacement from its starting point?

Extra Math Problems

- 23. An ant travels 75 cm in 5 s. What was the ant's speed?
- 24. It took you 6.5 h to drive 550 km. What was your speed?
- 25. A bus leaves at 9 A.M. with a group of tourists. They travel 350 km before they stop for lunch. Then they travel an additional 250 km until the end of their trip at 3 P.M. What was the average speed of the bus?
- 26. Halfway through a cross-country meet, a runner's speed is 4 m/s. In the last stretch, she increases her speed to 7 m/s. What is her change in speed?
- 27. It takes a car one minute to go from rest to 30 m/s. What is the acceleration of this car?
- 28. You are running at a speed of 10 km/h and hit a patch of mud. Two seconds later your speed is 8 km/h. What is your acceleration in units of m/s^2 ?
- 29. During a tug-of-war, Team A is applying a force of 5000 N while Team B is applying a force of 8000 N. What is the net force applied to the rope?
- 30. You are in a car traveling an average speed of 60 km/h. The total trip is 240 km. How long does the trip take?
- 31. You are riding in a train that is traveling at a speed of 120 km/h. How long will it take to travel 950 km?
- 32. A car goes from rest to a speed of 90 km/h in 10 s. What is the car's acceleration in m/s^2 ?
- 33. A cart rolling at a speed of 10 m/s comes to a stop in 2 s. What is the cart's acceleration?
- 38. If you are pushing on a box with a force of 20 N and there is a force of 7 N on the box due to sliding friction, what is the net force on the box?
- 39. The acceleration due to gravity on the moon is about 1.6 m/s^2 . If you weigh 539 N on Earth, how much would you weigh on the moon?
- 40. If a 5000-kg mass is moving at a speed of 43 m/s, what is its momentum?
- 41. How fast must a 50-kg mass travel to have a momentum of 1500 kg m/s?
- 42. What is the net force on a 4000-kg car that doubles its speed from 15 m/s to 30 m/s over 10 seconds?
- 43. A book with a mass of 1 kg is sliding on a table. If the frictional force on the book is 5 N, calculate the book's acceleration. Is it speeding up or slowing down?
- 44. What is the weight of a person with a mass of 80 kg?
- 45. A car with a mass of 1,200 kg has a speed of 30 m/s. What is the car's momentum?

Chapter 5 Energy

- 46. What is the kinetic energy of a 5-kg object moving at 7 m/s?
- 47. An object has kinetic energy of 600 J and a speed of 10 m/s. What is its mass?
- 48. If you throw a 0.4-kg ball at a speed of 20 m/s, what is the ball's kinetic energy?
- 49. A rollercoaster car moving around a high turn has 100,000 J of GPE and 23,000 J of KE. What is its mechanical energy?
- 50. If you have a mass of 80 kg and you are standing on a platform 3 m above the ground, what is your gravitational potential energy?
- 51. A car is traveling at 30 m/s with a kinetic energy of 900 kJ. What is its mass?
- 52. At top of a hill, a rollercoaster has 67,500 J of kinetic energy and 290,000 J of potential energy. Gradually the roller coaster comes to a stop due to friction. If the roller coaster has 30,000 J of potential when it stops, how much heat energy is generated by friction from the top of the hill until it stops?

Chapter 4 The Laws of Motion

- 34. A 85-kg mass has an acceleration of 5.5 m/s^2 . What is the net force applied?
- 35. A 3200-N force is applied to a 160-kg mass. What is the acceleration of the mass?
- 36. A 2-kg object is dropped from a height of 1000 m. What is the force of air resistance on the object when it reaches terminal velocity?
- 37. How much force is needed to lift a 25-kg mass?

53. A 2-kg book is moved from a shelf that is 2 m off the ground to a shelf that is 1.5 m off the ground. What is its change in GPE?
54. A system has a total mechanical energy of 350 J and kinetic energy of 220 J. What is its potential energy?
55. An object held in the air has a GPE of 470 J. The object then is dropped. Halfway down, what is the object's kinetic energy?
56. A car with a mass of 900 kg is traveling at a speed of 25 m/s. What is the kinetic energy of the car in joules?
57. What is the gravitational potential energy of a diver with a mass of 60 kg who is 10 m above the water?
58. If your weight is 500 N, and you are standing on a floor that is 20 m above the ground, what is your gravitational potential energy?

Chapter 6 Work and Machines

59. When moving a couch, you exert a force of 400 N and push it 4 m. How much work have you done?
60. How much work is needed to lift a 50-kg weight to a shelf 3 m above the floor?
61. By applying a force of 50 N, a pulley system can lift a box with a mass of 20 kg. What is the mechanical advantage of the pulley system?
62. How much energy do you save per hour if you replace a 60-watt lightbulb with a 55-watt lightbulb?
63. Suppose you supply energy to a machine at a rate of 700 W and that the machine converts 560 J into heat every second. At what rate does the machine do work?
64. You exert a force of 200 N on a machine over a distance of 0.3 m. If the machine moves an object a distance of 0.5 m, how much force does the machine exert on the object? Assume friction can be ignored.
65. What is the efficiency of a machine if you do work on the machine at a rate of 1200 W and the machine does work at a rate of 300 W?
66. What is the IMA of a seesaw with a 1.6-m effort arm and a 1.2-m resistance arm?
67. What is the IMA of a wheel with a radius of 0.35 m and an axle radius of 0.04 m?
68. An inclined plane has an IMA of 1.5 and a height of 2.0 m. How long is this inclined plane?
69. What power is used by a machine to perform 800 J of work in 25 s?
70. A person pushes a box up a ramp that is 3 m long, and 1 m high. If the box has a mass of 20 kg, and the person pushes with a force of 80 N, what is the efficiency of the ramp?
71. A first class lever has a mechanical advantage of 5. How large would a force need to be to lift a rock with a mass of 100 kg?

Chapter 7 The Earth-Moon-Sun System

72. Earth's diameter is 12,714 km from pole to pole and 12,756 km at the equator. How much less is Earth's diameter from pole to pole than that at the equator?
73. Earth's circumference is 40,075 km at the equator and 40,008 km through the two poles. How much greater is Earth's circumference around the equator?
74. Earth's average density is 5.52 g/cm^3 . If the Moon's average density is 3.31 g/cm^3 , what percentage of Earth's density is the Moon's density?
75. If a day on Earth lasts 23 h and 56 min, how many minutes are in one day?
76. Earth is one AU (149,600,000 km) from the Sun. If Jupiter is 5.2 AUs from the Sun, how many kilometers is Jupiter from the Sun?
77. If Earth rotates 15° each hour, how many degrees will it rotate in three hours?
78. Earth is tilted 23.5° . If the Sun is 50° above the southern horizon when it is directly over the equator, how high in the sky will the Sun be on the first day of summer?
79. If the Sun has a diameter of 1,392,000 km and is about 400 times larger than the Moon, what is the approximate diameter of the Moon?

Extra Math Problems

- 80. If there are 29.5 days in one synodic month, how many synodic months are there in one year of 365 days?
- 81. The South Pole-Aitken Basin on the Moon is 12 km deep and 2,500 km wide. How many times wider is the basin than it is deep?

Chapter 8 The Solar System

- 82. What fraction of a complete orbit (360°) would a planet move through if its H.L. changes from 32° to 302° ?
- 83. What fraction of a complete orbit (360°) would a planet move through if its H.L. changes from 152° to 242° ?
- 84. Earth's atmospheric pressure is 101.3 kPa. What is atmospheric pressure on the surface of Titan if it is 1.5 times that of Earth's?
- 85. What is the atmospheric pressure on the surface of Mars if it is 0.6 percent of Earth's?
- 86. If the atmospheric pressure of Triton's atmosphere is 0.002 percent of Earth's, what is the atmospheric pressure on the surface of Triton?
- 87. If a planet has an H.L. of 73° , what percentage of the total orbit (360°) would this represent?
- 88. If the diameters of Earth and Uranus are 12,756 km and 51,118 km respectively, approximately how many Earths could fit across Uranus's diameter?
- 89. The volume of sphere is $\frac{4}{3}(\pi r^3)$. If the radius of Earth is 6,378 km and the radius of Jupiter is 71,492, how many Earths would fit inside Jupiter?
- 90. The volume of sphere is $\frac{4}{3}(\pi r^3)$. If the radius of Mars is 3,394 km and the radius of Earth is 6,378 km, what percentage of Earth's volume is Mars's volume?
- 91. On average, Earth is 150 million km (1 AU) from the Sun. If Saturn is 9.53 AU from the Sun, what is the distance from the Sun to Saturn?
- 92. If Venus takes 0.62 years to orbit the Sun and Saturn takes 29.42 years to orbit the Sun, how many times will Venus orbit the Sun during each orbit of Saturn?

- 93. If Earth is tilted 23.5° and Uranus is tilted 97.9° , how many times greater is the axial tilt of Uranus than that of Earth?

Chapter 9 Heat and States of Matter

- 94. Water has a specific heat of 4184 J/(kg K). How much energy is needed to increase the temperature of a kilogram of water 5°C ?
- 95. The temperature of a block of iron, which has a specific heat of 450 J/(kg K), increases by 3 K when 2700 J of energy are added to it. What is the mass of this block of iron?
- 96. How much energy is needed to heat 1 kg of sand, which has a specific heat of 664 J/(kg K), from 30°C to 50°C ?
- 97. 1 kg of water (specific heat = 4184 J/(kg K)) is heated from freezing (0°C) to boiling (100°C). What is the change in thermal energy?
- 98. A concrete statue (specific heat = 600 J/(kg K)) sits in sunlight and warms up to 40°C . Overnight, it cools to 15°C and loses 90,000 J of thermal energy. What is its mass?
- 99. A glass of water has temperature of 70°C . What is its temperature in K?
- 100. A substance with a mass of 10 kg loses 106.5 kJ of heat when its temperature drops 15°C . What is this substance's specific heat?
- 101. Air is cooled from room temperature (25°C) to 100 K. What is the temperature change in K?
- 102. To remove 800 J of heat from a refrigerator, the compressor in the refrigerator does 500 J of work. How much heat is released into the surrounding room?
- 103. How much heat is needed to raise the temperature of 100 g of water by 50 K, if the specific heat of water is 4,184 J/kg K?
- 104. A sample of an unknown metal has a mass of 0.5 kg. Adding 1,985 J of heat to the metal raises its temperature by 10 K. What is the specific heat of the metal?

Chapter 10 Waves

- 105. What is the wavelength of a wave with a frequency of 0.4 kHz traveling at 16 m/s?

106. Two waves are traveling in the same medium with a speed of 340 m/s. What is the difference in frequency of the waves if the one has a wavelength of 5 m and the other has a wavelength of 0.2 m?
107. Transverse wave A has an amplitude of 7 cm. This wave constructively interferes with wave B. While the two waves overlap, the amplitude of the resulting wave is 10 cm. What is the amplitude of wave B?
108. What is the wavelength of a wave with a frequency of 5 Hz traveling at 15 m/s?
109. What is the velocity of a wave that has a wavelength of 6 m and a frequency of 3 Hz?
110. A ray of light hits a mirror at an angle of 35° to the normal. What is the angle of the reflected ray to the normal?
111. A wave has a wavelength of 250 cm and a frequency of 4 Hz. What is its speed?
112. A wave has a frequency of 5.6 MHz. What is the frequency of this wave in Hz?
113. A light ray strikes a mirror and is reflected. The angle between the incident and reflected rays is 86° . What is the angle of the incident ray to the normal?
114. What is the frequency of a wave with a wavelength of 7 m traveling at 21 m/s?

Chapter 11 Sound and Light

115. A sound wave with a frequency of 440 Hz travels in steel with a speed of 5200 m/s. What is the wavelength of the sound wave?
116. A wave traveling in water has a wavelength of a 750 m and a frequency of 2 Hz. How fast is this wave moving?
117. At 0°C sound travels through air with a speed of about 331 m/s and through aluminum with a speed of 4877 m/s. How many times longer is the wavelength of a sound wave in aluminum compared to the wavelength of a sound wave in air if both waves have the same frequency?

118. The speed of sound in air at 0°C is 331 m/s, and at 20°C is 344 m/s. What is the percentage change in the speed of sound at 20°C compared to 0°C ?
119. The wreck of the *Titanic* is at a depth of about 3800 m. A sonar unit on a ship above the *Titanic* emits a sound wave that travels at a speed of 1500 m/s. How long does it take a sound wave reflected from the *Titanic* to return to the ocean surface?
120. A sonar unit on a ship emits a sound wave. The echo from the ocean floor is detected two seconds later. If the speed of sound in water is 1500 m/s, how deep is the ocean beneath the ship?
121. A tsunami travels across the ocean at a speed of 500 km/h. If the distance between the wave crests is 200 km, what is the frequency of the wave?
122. A light ray strikes a plane mirror. The angle between the light ray and the surface of the mirror is 25° . What angle does the reflected ray make with the normal?
123. If the index of refraction of the mineral rock salt is 1.52, and the speed of light in a vacuum is 300,000 km/s, what is the speed of light in rock salt?
124. In the human eye, there are about 7,000,000 cone cells distributed over an area of 5 cm^2 . If cone cells are evenly distributed over this region, how many cone cells are distributed over an area of 2 cm^2 ? Express your answer in scientific notation.
125. The magnification of a mirror or lens equals the image size divided by the object size. If a plant cell with a diameter of 0.0035 mm is magnified so that the diameter of the image is 0.028 cm, what is the magnification?
126. Light enters the human eye through the pupil. In the dark, the pupil is dilated and has a diameter of about 1 cm. The Keck telescope has a mirror with a diameter of 10 m. If both the pupil and the Keck mirror are circles, what is the ratio of the area of the Keck telescope mirror to the area of a dilated human pupil?

Extra Math Problems

127. A light source is placed a distance of 1.2 m from a concave mirror on the optical axis. The reflected light rays are parallel and form a light beam. What is the focal length of the mirror?

Chapter 12 Earth's Internal Processes

128. How long after an earthquake will a seismograph 3,000 km away from the epicenter record S-waves that travel at 3.6 km/s?
129. If it takes 48 min and 20 s for P-waves traveling at 6.0 km/s to reach and be recorded by a seismograph, how far away is the epicenter?
130. If S-waves lag behind P-waves by 1 min 52 s for every 1000 km of distance from the earthquake epicenter, how far away from the earthquake epicenter is a seismograph that measures a time-lag of 5 min 30 s between the arrivals of P-waves and S-waves?
131. With a P-wave-S-wave lag time of 1 min 52 sec, how much difference between the arrival times of P-waves and S-waves would be measured at 3,000 km? At 3,500 km?
132. If surface waves travel at 3.2 km/s, when would you expect them to arrive at a seismograph that is 2,500 km distant from the earthquake epicenter?
133. If S-waves travel at 3.6 km/s and P-waves travel at 6.0 km/s through Earth's crust, what percentage of the speed of P-waves would you expect S-waves to travel at other depths inside Earth?
134. The volume of a cone is $\frac{1}{3}\pi r^2 h$. If Parícutín is 424 m high and has a base 2.8 km across, what is the volume of the cinder cone?
135. If two plates diverge at a rate of 1.3 cm/year, how much farther apart in kilometers will the two plates be after 200 million years?
136. How many times faster are plates moving at 7.3 cm/year than are plates moving at 1.3 cm/year?
137. The volume of a sphere is $\frac{4}{3}(\pi r^3)$. The radius of Earth is 6,378 km, and the radius of its core (including both outer and inner cores) is 3,486 km. What are the volumes of both? What percentage of the total volume of Earth is its core?

Chapter 13 Electricity

138. A circuit has a resistance of 4 Ω . What voltage difference will cause a current of 1.4 A to flow in the circuit?
139. How many amperes of current will flow in a circuit if the voltage difference is 9 V and the resistance in the circuit is 3 Ω ?
140. If a voltage difference of 3 V causes a 1.5 A current to flow in a circuit, what is the resistance in the circuit?
141. The current in an appliance is 3 A and the voltage difference is 120 V. How much power is being supplied to the appliance?
142. What is the current into a microwave oven that requires 700 W of power if the voltage difference is 120 V?
143. What is the voltage difference in a circuit that uses 2420 W of power if 11 A of current flows into the circuit?
144. How much energy is used when a 110 kW appliance is used for 3 hours?
145. A television has a power rating of 210 W. If the television uses 1.68 kWh of energy, for how long has the television been on?
146. How much does it cost to light six 100-W lightbulbs for six hours if the price of electrical energy is \$0.09/kWh?
147. An electric clothes dryer uses 4 kW of electric power. How long did it take to dry a load of clothes if electric power costs \$0.09/kWh, and the cost of using the dryer was \$0.27?
148. What is the resistance of a lightbulb that draws 0.5 amp of current when plugged into a 120-V outlet?
149. How much current flows through a 100-W lightbulb that is plugged into a 120-V outlet?
150. Eight amps of current flow through a hair dryer connected to a 120-V outlet. How much electrical power does the hair dryer use?
151. Compare the electrical energy that is used by a 100-W lightbulb that burns for 10 h, and a 1,200-W hair dryer that is used for 15 min.

Chapter 14 Magnetism

152. How many turns are in the secondary coil of a step-down transformer that reduces a voltage from 900 V to 300 V and has 15 turns in the primary coil?
153. A step-down transformer reduces voltage from 2400 V to 120 V. What is the ratio of the number of turns in the primary coil to the number of turns in the secondary coil of the transformer?
154. The current produced by an AC generator switches direction twice for each revolution of the coil. How many times does a 110-Hz alternating current switch direction each second?
155. What is the output voltage from a step-down transformer with 200 turns in the primary coil and 100 turns in the secondary coil if the input voltage was 750 V?
156. What is the output voltage from a step-up transformer with 25 turns in the primary coil and 75 turns in the secondary coil if the input voltage was 120 V?
157. How many turns are in the primary coil of a step-down transformer that reduces a voltage from 400 V to 100 V and has 80 turns in the secondary coil?
158. How many turns are in the secondary coil of a step-up transformer that increases voltage from 30 V to 150 V and has seven turns in the primary coil?
159. The coil of a 60-Hz generator makes 60 revolutions each second. How many revolutions does the coil make in five minutes?
160. If a generator coil makes 6000 revolutions in two minutes, how many revolutions does it make each second?

Chapter 15 Electromagnetic Radiation

161. Express the number 20,000 in scientific notation.
162. An electromagnetic wave has a wavelength of 0.054 m. What is the wavelength in scientific notation?

163. Earth is about 4,500,000,000 years old. Express this number in scientific notation.
164. The speed of electromagnetic waves in air is 300,000 km/s. What is the frequency of electromagnetic waves that have a wavelength of 5×10^{-3} km?
165. The speed of radio waves in water is about 2.26×10^5 km/s. What is the frequency of radio waves that have a wavelength of 3.0 km?
166. Radio waves with a frequency of 125,000 Hz have a wavelength of 1.84 km when traveling in ice. What is the speed of the radio waves in ice?
167. Some infrared waves have a frequency of 10,000,000,000,000 Hz. Express this frequency in scientific notation.
168. An infrared wave has a frequency of 1×10^{13} Hz and a wavelength of 3×10^{-5} m. Express this wavelength as a decimal number.
169. An AM radio station broadcasts at a frequency of 620 kHz. Express this frequency in Hz using scientific notation.
170. An FM radio station broadcasts at a frequency of 101 MHz. Express this frequency in Hz using scientific notation.

Chapter 16 Energy Sources

171. A gallon of gasoline contains about 2800 g of gasoline. If burning one gram of gasoline releases about 48 kJ of energy, how much energy is released when a gallon of gasoline is burned? (1 kJ = 1000 J)
172. An automobile engine converts the energy released by burning gasoline into mechanical energy with an efficiency of about 25%. If burning 1 kg of gasoline releases about 48,000 kJ of energy, how much mechanical energy is produced by the engine when 1 kg of gasoline is burned?
173. You heat a cup of water in a 750-W microwave oven for 40 s, and warm the water by 20°C. If it takes about 20 kJ of energy to raise the temperature of a cup of water by 20°C, what is the efficiency of the microwave oven?

Extra Math Problems

- 174. On average, solar energy strikes Earth's surface with an intensity of about 200 W/m^2 . If solar cells are 10% efficient, how large an area would have to be covered by solar cells to generate enough electrical power to light a 100-W lightbulb?
- 175. What is the overall efficiency of a hydroelectric plant if the process of falling water turning a turbine is 80% efficient, the turbine spinning an electric generator is 95% efficient, and the transmission through power lines is 90% efficient?
- 176. When a certain $^{235}_{92}\text{U}$ nucleus is struck by a neutron, it forms the two nuclei $^{91}_{36}\text{Kr}$ and $^{142}_{56}\text{Ba}$. How many neutrons are emitted when this occurs?
- 177. A nuclear reactor contains 100,000 kg of enriched uranium. About 4% of the enriched uranium is the isotope uranium-235. What is the mass of uranium-235 in the reactor core?
- 178. Suppose the number of uranium-235 nuclei that are split doubles at each stage of a chain reaction. If the chain reaction starts with one nucleus split in the first stage, how many nuclei will have been split after six stages?
- 179. From 1970 to 1995 the carbon dioxide concentration in Earth's atmosphere increased from about 325 parts per million to about 360 parts per million. What was the percentage change in the concentration of carbon dioxide?
- 180. About 85% of the energy used in the U.S. comes from fossil fuels. How many times greater is the amount of energy used from fossil fuel than the amount used from all other energy sources?
- 183. Air pressure at Earth's surface is 101.3 kPa. What is the air pressure at 16 km if it is $\frac{1}{10}$ the air pressure at Earth's surface?
- 184. Much of northern Florida receives 1,300 mm of rain on average per year and the southern part of the Everglades receives 1,650 mm of rain on average per year. What percentage is the rainfall in northern Florida of the rainfall in the southern part of the Everglades?
- 185. If the tilt of Earth's axis has varied from 21.5° to 24.5° over time, what is the value of the range of Earth's axial tilt?
- 186. Air pressure at Earth's surface is 101.3 kPa. If air pressure in an average car tire is equal to two atmospheres, what is the pressure in an average car tire?
- 187. Most of Earth's atmosphere is within 30 km of Earth's surface. If Earth's atmosphere extends about 10,000 km above Earth's surface, what percentage of the atmosphere's depth contains most of Earth's atmosphere?
- 188. If a tornado travels at 50 km/h and cuts a path of destruction 10 km long, how many minutes did it take to do this?
- 189. If there have been eight glacial periods during the past 200,000 years, what is the rate at which these have occurred?
- 190. The three main gases in Earth's atmosphere are nitrogen—78 percent, oxygen—21 percent, and argon and trace gases—1 percent. If a circle graph were drawn to represent these data, how many degrees would represent each section?

Chapter 17 Weather and Climate

- 181. If a snowy surface reflects 90 percent of the solar radiation that strikes it and bare soil reflects 30 percent, how many times more solar radiation is reflected from a snowy surface than from bare soil?
- 182. The amount of rainfall over five days is 4 cm, 2 cm, 0.4 cm, 0.2 cm, and 1.3 cm. What is the average rainfall per day?

Chapter 18 Classification of Matter

- 191. Two solutions, one with a mass of 450 g and the other with a mass of 350 g, are mixed. A chemical reaction occurs and 125 g of solid crystals are produced that settle on the bottom of the container. What is the mass of the remaining solution?

192. Carbon reacts with oxygen to form carbon dioxide according to the following equation: $C + O_2 \rightarrow CO_2$. When 120 g of carbon reacts with oxygen, 440 g of carbon dioxide are formed. How much oxygen reacted with the carbon?
193. Salt water is distilled by boiling it and condensing the vapor. After distillation, 1,164 g of water have been collected and 12 g of salt are left behind in the original container. What was the original mass of the salt water?
194. Calcium carbonate, $CaCO_3$, decomposes according to the reaction: $CaCO_3 \rightarrow CaO + CO_2$. When 250 g of $CaCO_3$ decompose completely, the mass of CaO is 56% of the mass of the products of this reaction. What is the mass of CO_2 produced?
195. Water breaks down into hydrogen gas and oxygen gas according to the reaction: $2H_2O \rightarrow 2H_2 + O_2$. In this reaction the mass of oxygen produced is eight times greater than the mass of hydrogen produced. If 36 g of water form hydrogen and oxygen gas, what is the mass of hydrogen gas produced?
196. The size of particles in a solution is about 1 nm (1 nm = 0.000000001 m). Write 0.000000001 m in scientific notation.
197. A chemical reaction produces two new substances, one with a mass of 34 g and the other with a mass of 39 g. What was the total mass of the reactants?
198. The human body is about 65% oxygen. If a person has a mass of 75.0 kg, what is the mass of oxygen in their body?
199. A 112-g serving of ice cream contains 19 g of fat. What percentage of the serving is fat?
200. The mass of the products produced by a chemical reaction is measured. The reaction is repeated five times, with the same mass of reactants used each time. The measured product masses are 50.17 g, 50.12 g, 50.17 g, 50.10 g, and 50.14 g. What is the average of these measurements?

Chapter 19 Properties of Atoms and the Periodic Table

201. Boron has a mass number of 11 and an atomic number of 5. How many neutrons are in a boron atom?
202. A magnesium atom has 12 protons and 12 neutrons. What is its mass number?
203. Iodine-127 has a mass number of 127 and 74 neutrons. What percentage of the particles in an iodine-127 nucleus are protons?
204. How many neutrons are in an atom of phosphorus-31?
205. What is the ratio of neutrons to protons in the isotope radium-234?
206. About 80% of all magnesium atoms are magnesium-24, about 10% are magnesium-25, and about 10% are magnesium-26. What is the average atomic mass of magnesium?
207. The half-life of the radioactive isotope rubidium-87 is 48,800,000,000 years. Express this half-life in scientific notation.
208. The radioactive isotope nickel-63 has a half-life of 100 years. How much of a 10.0-g sample of nickel-63 is left after 300 years?
209. A sample of the radioactive isotope cobalt-62 is prepared. The sample has a mass of 1.00 g. After three minutes, the mass of cobalt-62 remaining is 0.25 g. What is the half-life of cobalt-62?
210. A neutral phosphorus atom has 15 electrons. How many electrons are in the third energy level?

Chapter 20 Earth Materials

211. If oxygen makes up 46.6 percent of the mass of Earth's crust and silicon makes up 27.7 percent, what is the total percent of the crust's mass for oxygen and silicon?
212. If oxygen and silicon make up 74.3 percent of the mass of Earth's crust, what percent of this percentage is silicon's percentage?
213. How many total atoms of aluminum and oxygen combined make up one molecule of corundum (Al_2O_3)?

Extra Math Problems

- 214. What is the ratio of silicon to oxygen in a molecule of olivine $((\text{Mg}, \text{Fe})_2\text{SiO}_4)$?
- 215. Other than the common eight elements that make up Earth's crust, all other elements make up only 1.5 percent. If oxygen makes up 46.6 percent of Earth's crust, how many times greater is the amount of oxygen in Earth's crust than those other elements.
- 216. The Mohs scale of hardness consists of ten categories, each associated with a mineral standard. How many categories are between hardness 7—quartz and hardness 2—gypsum?
- 217. The volume of sphere is $\frac{4}{3} \pi r^3$. If a particle of gravel has a radius of 2 mm and a sand grain has a radius of 1 mm, how much bigger is the volume of the gravel?
- 218. If a sedimentary rock has a porosity of 15 percent, how much volume do the mineral grains and cement take up?
- 219. If you have a halite cube that measures 4 cm on each side, what is the total surface area of the cube?
- 220. What is the ratio of oxygen atoms to potassium atoms in one molecule of K-feldspar, $(\text{KAlSi}_3\text{O}_8)$?
- 225. Observations taken at the mouth of a stream include a flow rate of $85 \text{ m}^3/\text{s}$ and a suspended sediment load of 1.6 kg/m^3 . How many kilograms of sediment potentially could drop out of this stream each day?
- 226. Suppose a community with a human population of 800 has a water consumption rate of 900 L per person per day. This community relies on an aquifer that is thought to contain 1.2 billion L of water. Assuming no change in average water consumption or significant recharge of the aquifer, how many years will this water supply last?
- 227. An aquifer is 400 km in length, 185 km in width, and 80 km thick. Sampling of the aquifer material shows it has an average porosity of 15 percent. What is the volume of porosity?
- 228. An aquifer with dimensions of 350 km in length, 175 km in width, and 65 km thick. Sampling of the aquifer material shows it has an average porosity of 10 percent. What is the volume of porosity?
- 229. If three half-lives for an isotope have passed, what fraction of the original isotope would be present in the igneous rock?
- 230. If the half-life of an isotope is 12,000 years and the amount of the isotope present in the rock is only $\frac{1}{16}$ of the original amount present, how old is the igneous rock containing the isotope?

Chapter 21 Earth's Changing Surface

- 221. If soil erosion averages 2.5 cm per year and the average soil profile is 3.2 m thick with 40 percent of topsoil, how long will it take for the topsoil to erode away?
- 222. The average soil profile in your area is 2.1 m thick. Topsoil erodes at 2.0 cm per year. What percent of the soil profile is topsoil if it erodes in 14 years?
- 223. Soil erosion in your area averages 3.5 cm per year. The average soil profile is 3.7 m thick and 35 percent of that is topsoil. Soil replacement through weathering is 0.2 cm per year. How long will it take for the topsoil to erode?
- 224. Observations taken at the mouth of a stream include a flow rate of $120 \text{ m}^3/\text{s}$ and a suspended sediment load of 1.8 kg/m^3 . How many kilograms of sediment potentially could drop out of this stream each day?

Chapter 22 Chemical Bonds

- 231. What is the formula of the compound formed when ammonium ions, NH_4^+ , and phosphate ions, PO_4^{3-} , combine?
- 232. Show that the sum of positive and negative charges in a unit of calcium chloride (CaCl_2) equals zero.
- 233. What is the formula for iron(III) oxide?
- 234. How many hydrogen atoms are in three molecules of ammonium phosphate, $(\text{NH}_4)_3\text{PO}_4$?
- 235. The overall charge on the polyatomic phosphate ion, PO_4^{3-} , is 3-. What is the oxidation number of phosphorus in the phosphate ion?

236. The overall charge on the polyatomic dichromate ion, $\text{Cr}_2\text{O}_7^{2-}$, is 2-. What is the oxidation number of chromium in this polyatomic ion?
237. What is the formula for lead(IV) oxide?
238. What is the formula for potassium chlorate?
239. What is the formula for carbon tetrachloride?
240. What percentage of the mass of a sulfuric acid molecule, H_2SO_4 , is sulfur?

Chapter 23 Chemical Reactions

241. Lithium reacts with oxygen to form lithium oxide according to the equation: $4\text{Li} + \text{O}_2 \rightarrow 2\text{Li}_2\text{O}$. If 27.8 g of Li react completely with 32.0 g of O_2 , how many grams of Li_2O are formed?
242. What coefficients balance the following equation: $_\text{Zn}(\text{OH})_2 + _\text{H}_3\text{PO}_4 \rightarrow _\text{Zn}_3(\text{PO}_4)_2 + _\text{H}_2\text{O}$?
243. Aluminum hydroxide, $\text{Al}(\text{OH})_3$, decomposes to form aluminum oxide, Al_2O_3 , and water according to the reaction: $2\text{Al}(\text{OH})_3 \rightarrow \text{Al}_2\text{O}_3 + 3\text{H}_2\text{O}$. If 156.0 g of $\text{Al}(\text{OH})_3$ decompose to form 102.0 g of Al_2O_3 , how many grams of H_2O are formed?
244. In the following balanced chemical reaction one of the products is represented by the symbol X: $\text{BaCO}_3 + \text{C} + \text{H}_2\text{O} \rightarrow \text{Ba}(\text{OH})_2 + \text{H}_2\text{O} + 2\text{X}$. What is the formula for the compound represented by X?
245. When propane, C_3H_8 , is burned, carbon dioxide and water vapor are produced according to the following reaction: $\text{C}_3\text{H}_8 + 5\text{O}_2 \rightarrow 3\text{CO}_2 + 4\text{H}_2\text{O}$. How much propane is burned if 160.0 g of O_2 are used and 132.0 g of CO_2 and 72.0 g of H_2O are produced?
246. Increasing the temperature usually causes the rate of a chemical reaction to increase. If the rate of a chemical reaction doubles when the temperature increases by 10°C , by what factor does the rate of reaction increase if the temperature increases by 30°C ?

247. When acetylene gas, C_2H_2 , is burned, carbon dioxide and water are produced. Find the coefficients that balance the chemical equation for the combustion of acetylene:
 $_\text{C}_2\text{H}_2 + _\text{O}_2 \rightarrow _\text{CO}_2 + _\text{H}_2\text{O}$.
248. What coefficients balances the following equation: $_\text{CS}_2 + _\text{O}_2 \rightarrow _\text{CO}_2 + _\text{SO}_2$?
249. When methane, CH_4 , is burned, 50.1 kJ of energy per gram are released. When propane, C_3H_8 , is burned, 45.8 kJ of energy are released. If a mixture of 1 g of methane and 1 g of propane is burned, how much energy is released per gram of mixture?
250. A chemical reaction produces 0.050 g of a product in 0.18 s. In the presence of a catalyst, the reaction produces 0.050 g of the same product in 0.007 s. How much faster is the rate of reaction in the presence of the enzyme?

Chapter 24 Solutions, Acids, and Bases

251. A cup of orange juice contains 126 mg of vitamin C and 1/2 cup of strawberries contain 42 mg of vitamin C. How many cups of strawberries contain as much vitamin C as one cup of orange juice?
252. What is the total surface area of a 2-cm cube?
253. A cube has 2-cm sides. If it is split in half, what is the total surface area of the two pieces?
254. At 20°C , the solubility in water of potassium bromide, KBr, is 65.3 g/100 mL. What is the maximum amount of potassium bromide that will dissolve in 237 mL of water?
255. At 20°C , the solubility of sodium chloride, NaCl, in water is 35.9 g/100 mL. If the maximum amount of sodium chloride is dissolved in 500 mL of water at 20°C , the mass of the dissolved sodium chloride is what percentage of the mass of the solution?
256. The difference between the pH of an acidic solution and the pH of pure water is 3. What is the pH of the solution?

257. The pH of rain that fell over a region had measured values of 4.6, 5.1, 4.8, 4.5, 4.5, 4.9, 4.7, and 4.8. What was the mean value of the measured pH?
 258. If 5.5% of 473.0 mL of vinegar is acetic acid, how many milliliters of acetic acid are there?
 259. Write the balanced chemical equation for the neutralization of H_2SO_4 , sulfuric acid, by KOH, potassium hydroxide.
 260. Write the balanced chemical equation for the neutralization of HBr, hydrobromic acid, by $\text{Al}(\text{OH})_3$, aluminum hydroxide.

Chapter 25 Nuclear Changes

261. How many protons are in the nucleus $^{81}_{36}\text{Kr}$?
 262. How many neutrons are in the nucleus $^{56}_{26}\text{Fe}$?
 263. What is the ratio of neutrons to protons in the nucleus $^{241}_{95}\text{Am}$?
 264. How many alpha particles are emitted when the nucleus $^{222}_{86}\text{Rn}$ decays to $^{218}_{84}\text{Po}$?
 265. How many beta particles are emitted when the nucleus $^{40}_{19}\text{K}$ decays to the nucleus $^{40}_{20}\text{Ca}$?
 266. An alpha particle is the same as the helium nucleus ^4_2He . What nucleus is produced when the nucleus $^{226}_{88}\text{Ra}$ decays by emitting an alpha particle?
 267. How long will it take a sample of $^{194}_{84}\text{Po}$ to decay to 1/8 of its original amount if $^{194}_{84}\text{Po}$ has a half-life of 0.7 s?
 268. The half-life of $^{131}_{53}\text{I}$ is 8.04 days. How much time would be needed to reduce 1 g of $^{131}_{53}\text{I}$ to 0.25 g?
 269. A sample of radioactive carbon-14 sample has decayed to 12.5% of its original amount. If the half-life of carbon-14 is 5730 years, how old is this sample?
 270. A sample of $^{38}_{17}\text{Cl}$ is observed to decay to 25% of the original amount in 74.4 minutes. What is the half-life of $^{38}_{17}\text{Cl}$?

Chapter 26 Stars and Galaxies

271. If the focal length of a telescope's objective is 900 mm and the focal length of its eyepiece is 10 mm, what is the magnifying power of this telescope?
 272. If the focal length of a telescope's objective is 700 mm and the magnifying power of the telescope is 40 times, what is the focal length of an eyepiece?
 273. If it takes 25 days for a sunspot to travel once around the Sun, about how many days would it take to travel across the face of the Sun?
 274. If a solar prominence blasts material from the Sun at a speed of 600 km/s, how long in hours and minutes would it take for material to arrive at Earth 150 million km away?
 275. How many times larger in area is a 250-mm-diameter objective than a 100-mm diameter objective?
 276. How many times larger in area is an 8-m-diameter objective than a 5-m-diameter objective?
 277. How many times larger is an elliptical galaxy that is nine million light-years across than one that is 3,000 light-years across?
 278. A telescope's objective has a focal length of 1,200 mm. It is used with two eyepieces that have focal lengths of 12 mm and 18 mm. How many times greater is the magnifying power of the telescope when the 12-mm eyepiece is used?
 279. A telescope's objective has a focal length of 1500 mm. It is used with two eyepieces that have focal lengths of 20 mm and 12.5 mm. What percentage of the magnifying power obtained using the 12.5-mm eyepiece is achieved using the 20-mm eyepiece?
 280. If the age of the universe was thought to be 20 billion years, but is now considered to be 13.7 billion years, how much younger is the universe thought to be now?

Rocks

Rocks		
Rock Type	Rock Name	Characteristics
Igneous (intrusive)	Granite	Large mineral grains of quartz, feldspar, hornblende, and mica. Usually light in color.
	Diorite	Large mineral grains of feldspar, hornblende, and mica. Less quartz than granite. Intermediate in color.
	Gabbro	Large mineral grains of feldspar, augite, and olivine. No quartz. Dark in color.
Igneous (extrusive)	Rhyolite	Small mineral grains of quartz, feldspar, hornblende, and mica, or no visible grains. Light in color.
	Andesite	Small mineral grains of feldspar, hornblende, and mica or no visible grains. Intermediate in color.
	Basalt	Small mineral grains of feldspar, augite, and possibly olivine or no visible grains. No quartz. Dark in color.
	Obsidian	Glassy texture. No visible grains. Volcanic glass. Fracture looks like broken glass.
	Pumice	Frothy texture. Floats in water. Usually light in color.
Sedimentary (detrital)	Conglomerate	Coarse grained. Gravel or pebble-size grains.
	Sandstone	Sand-sized grains 1/16 to 2 mm.
	Siltstone	Grains are smaller than sand but larger than clay.
	Shale	Smallest grains. Often dark in color. Usually platy.
Sedimentary (chemical or organic)	Limestone	Major mineral is calcite. Usually forms in oceans and lakes. Often contains fossils.
	Coal	Forms in swampy areas. Compacted layers of organic material, mainly plant remains.
Sedimentary (chemical)	Rock Salt	Commonly forms by the evaporation of seawater.
Metamorphic (foliated)	Gneiss	Banding due to alternate layers of different minerals, of different colors. Parent rock often is granite.
	Schist	Parallel arrangement of sheetlike minerals, mainly micas. Forms from different parent rocks.
	Phyllite	Shiny or silky appearance. May look wrinkled. Common parent rocks are shale and slate.
	Slate	Harder, denser, and shinier than shale. Common parent rock is shale.
Metamorphic (nonfoliated)	Marble	Calcite or dolomite. Common parent rock is limestone.
	Soapstone	Mainly of talc. Soft with greasy feel.
	Quartzite	Hard with interlocking quartz crystals. Common parent rock is sandstone.

Minerals

Minerals					
Mineral (formula)	Color	Streak	Hardness	Breakage Pattern	Uses and Other Properties
Graphite (C)	black to gray	black to gray	1–1.5	basal cleavage (scales)	pencil lead, lubricants for locks, rods to control some small nuclear reactions, battery poles
Galena (PbS)	gray	gray to black	2.5	cubic cleavage perfect	source of lead, used for pipes, shields for X rays, fishing equipment sinkers
Hematite (Fe ₂ O ₃)	black or reddish- brown	reddish- brown	5.5–6.5	irregular fracture	source of iron; converted to pig iron, made into steel
Magnetite (Fe ₃ O ₄)	black	black	6	conchoidal fracture	source of iron, attracts a magnet
Pyrite (FeS ₂)	light, brassy, yellow	greenish- black	6–6.5	uneven fracture	fool's gold
Talc (Mg ₃ Si ₄ O ₁₀ (OH) ₂)	white, greenish	white	1	cleavage in one direction	used for talcum powder, sculptures, paper, and tabletops
Gypsum (CaSO ₄ •2H ₂ O)	colorless, gray, white, brown	white	2	basal cleavage	used in plaster of paris and dry wall for building construction
Sphalerite (ZnS)	brown, reddish- brown, greenish	light to dark brown	3.5–4	cleavage in six directions	main ore of zinc; used in paints, dyes, and medicine
Muscovite (KAl ₃ Si ₃ O ₁₀ (OH) ₂)	white, light gray, yellow, rose, green	colorless	2–2.5	basal cleavage	occurs in large, flexible plates; used as an insulator in electrical equipment, lubricant
Biotite (K(Mg,Fe) ₃ (AlSi ₃ O ₁₀) (OH) ₂)	black to dark brown	colorless	2.5–3	basal cleavage	occurs in large, flexible plates
Halite (NaCl)	colorless, red, white, blue	colorless	2.5	cubic cleavage	salt; soluble in water; a preservative

Minerals

Minerals					
Mineral (formula)	Color	Streak	Hardness	Breakage Pattern	Uses and Other Properties
Calcite (CaCO ₃)	colorless, white, pale blue	colorless, white	3	cleavage in three directions	fizzes when HCl is added; used in cements and other building materials
Dolomite (CaMg (CO ₃) ₂)	colorless, white, pink, green, gray, black	white	3.5–4	cleavage in three directions	concrete and cement; used as an ornamental building stone
Fluorite (CaF ₂)	colorless, white, blue, green, red, yellow, purple	colorless	4	cleavage in four directions	used in the manufacture of optical equipment; glows under ultraviolet light
Hornblende (CaNa) ₂₋₃ (Mg,Al, Fe) ₅ -(Al,Si) ₂ Si ₆ O ₂₂ (OH) ₂)	green to black	gray to white	5–6	cleavage in two directions	will transmit light on thin edges; 6-sided cross section
Feldspar (KAlSi ₃ O ₈) (NaAl Si ₃ O ₈), (CaAl ₂ Si ₂ O ₈)	colorless, white to gray, green	colorless	6	two cleavage planes meet at 90° angle	used in the manufacture of ceramics
Augite ((Ca,Na) (Mg,Fe,Al) (Al,Si) ₂ O ₆)	black	colorless	6	cleavage in two directions	square or 8-sided cross section
Olivine ((Mg,Fe) ₂ SiO ₄)	olive, green	none	6.5–7	conchoidal fracture	gemstones, refractory sand
Quartz (SiO ₂)	colorless, various colors	none	7	conchoidal fracture	used in glass manufacture, electronic equipment, radios, computers, watches, gemstones

PERIODIC TABLE OF THE ELEMENTS

Columns of elements are called groups. Elements in the same group have similar chemical properties.

1	2	3	4	5	6	7	8	9
Hydrogen 1 H 1.008								
Lithium 3 Li 6.941	Beryllium 4 Be 9.012							
Sodium 11 Na 22.990	Magnesium 12 Mg 24.305							
Potassium 19 K 39.098	Calcium 20 Ca 40.078	Scandium 21 Sc 44.956	Titanium 22 Ti 47.867	Vanadium 23 V 50.942	Chromium 24 Cr 51.996	Manganese 25 Mn 54.938	Iron 26 Fe 55.845	Cobalt 27 Co 58.933
Rubidium 37 Rb 85.468	Strontium 38 Sr 87.62	Yttrium 39 Y 88.906	Zirconium 40 Zr 91.224	Niobium 41 Nb 92.906	Molybdenum 42 Mo 95.94	Technetium 43 Tc (98)	Ruthenium 44 Ru 101.07	Rhodium 45 Rh 102.906
Cesium 55 Cs 132.905	Barium 56 Ba 137.327	Lanthanum 57 La 138.906	Hafnium 72 Hf 178.49	Tantalum 73 Ta 180.948	Tungsten 74 W 183.84	Rhenium 75 Re 186.207	Osmium 76 Os 190.23	Iridium 77 Ir 192.217
Francium 87 Fr (223)	Radium 88 Ra (226)	Actinium 89 Ac (227)	Rutherfordium 104 Rf (261)	Dubnium 105 Db (262)	Seaborgium 106 Sg (266)	Bohrium 107 Bh (264)	Hassium 108 Hs (277)	Meitnerium 109 Mt (268)

State of matter

The first three symbols tell you the state of matter of the element at room temperature. The fourth symbol identifies elements that are not present in significant amounts on Earth. Useful amounts are made synthetically.

The number in parentheses is the mass number of the longest-lived isotope for that element.

Rows of elements are called periods. Atomic number increases across a period.

Lanthanide series

Actinide series

The arrow shows where these elements would fit into the periodic table. They are moved to the bottom of the table to save space.

Cerium 58 Ce 140.116	Praseodymium 59 Pr 140.908	Neodymium 60 Nd 144.24	Promethium 61 Pm (145)	Samarium 62 Sm 150.36
Thorium 90 Th 232.038	Protactinium 91 Pa 231.036	Uranium 92 U 238.029	Neptunium 93 Np (237)	Plutonium 94 Pu (244)

Metal

Metalloid

Nonmetal

The color of an element's block tells you if the element is a metal, nonmetal, or metalloid.

 s.....seed, cent (SEED, SENT)
 z.....zone, raise (ZOHN, RAYZ)

English

A

Español

absolute dating: process of assigning a precise numerical age to an organism, object, or event, based on an absolute reference. (p. 669)

acceleration: rate of change of velocity; can be calculated by dividing the change in the velocity by the time it takes the change to occur. (p. 76)

accuracy: compares a measurement to the real or accepted value. (p. 14)

☀ **acid:** any substance that produces hydrogen ions, H⁺, in a water solution. (p. 764)

☀ **activation energy:** the minimum amount of energy needed to start a reaction (p. 735)

agricultural biotechnology: scientific techniques, such as genetic engineering, used to increase farm crop yields and nutritional values of foods by creating, modifying, or improving plants, animals, and microorganisms. (p. 45)

air resistance: force that opposes the motion of objects that move through the air. (p. 85)

alpha particle: particle consisting of two protons and two neutrons that is emitted from a decaying atomic nucleus. (p. 791)

alternating current (AC): electric current that reverses its direction of flow in a regular pattern. (p. 442)

amplitude: maximum distance a wave causes the particles in a medium to move from the rest position. (p. 298)

datación absoluta: proceso de asignar una edad numérica precisa a un organismo, objeto o evento, basado en una referencia absoluta. (p. 669)

aceleración: tasa de cambio de la velocidad; se calcula dividiendo el cambio en la velocidad por el tiempo que toma para que ocurra el cambio. (p. 76)

exactitud: comparación de una medición con el valor real o aceptado. (p. 14)

ácido: sustancia que produce iones de hidrógeno, H⁺, en una solución de agua. (p. 764)

energía de activación: cantidad mínima de energía necesaria para comenzar una reacción. (p. 735)

biotecnología agrícola: técnicas científicas, como la ingeniería genética, utilizadas para incrementar la producción de las cosechas de las granjas y los valores nutricionales de los alimentos al crear, modificar o mejorar las plantas, animales y microorganismos. (p. 45)

resistencia del aire: fuerza que se opone al movimiento de los objetos que se mueven por el aire. (p. 85)

partícula alfa: partícula compuesta por dos protones y dos neutrones y que es emitida por un núcleo atómico en descomposición. (p. 791)

corriente alterna (CA): corriente eléctrica que invierte su dirección de flujo en un patrón regular. (p. 442)

amplitud: distancia máxima a la que una onda causa que las partículas en un medio salgan de su posición de reposo. (p. 298)

Glossary/Glosario

aqueous solution/biomass

- ☀ **aqueous solution:** a solution in which water is the solvent. (p. 753)
- aquifer:** rock unit that transmits water through its pore space. (p. 664)
- asteroids:** rocky solar system objects of widely varying size usually found between the orbits of Mars and Jupiter in an area called the asteroid belt. (p. 236)
- asthenosphere:** weaker, semi-solid, plasticlike layer beneath Earth's lithosphere on which lithospheric plates move. (p. 372)
- ☀ **astronomical unit:** about 150 million km, which equals the average distance from Earth to the Sun; used to measure distances within the solar system. (p. 220)
- atom:** the smallest particle of an element that still retains the properties of the element. (p. 589)
- ☀ **atomic number:** number of protons in an atom's nucleus. (p. 585)
- average atomic mass:** weighted-average mass of the mixture of an element's isotopes. (p. 587)
- average speed:** total distance an object travels divided by the total time it takes to travel that distance. (p. 72)

Solución acuosa/biomasa

- Solución acuosa:** solución en la que el agua es el solvente. (p. 753)
- Acuífero:** unidad rocosa que conduce agua a través de su espacio poroso. (p. 664)
- Asteroides:** objetos rocosos del sistema solar que varían ampliamente en tamaño y usualmente se encuentran entre las órbitas de Marte y Júpiter en un área llamada el cinturón de asteroides. (p. 236)
- astenosfera:** capa débil, semisólida, similar al plástico que se encuentra por debajo de la litosfera terrestre en la cual se mueven las placas litosféricas. (p. 372)
- unidad astronómica:** cerca de 150 millones de km, lo cual equivale a la distancia promedio de la tierra al sol; utilizada para medir distancias entre el sistema solar. (p. 220)
- átomo:** la partícula más pequeña de un elemento que mantiene las propiedades del elemento. (p. 589)
- número atómico:** número de protones en el núcleo de un átomo. (p. 585)
- masa atómica promedio:** masa de peso promedio resultado de la mezcla de los isótopos de un elemento. (p. 587)
- velocidad promedio:** distancia que recorre un objeto dividida por el tiempo que dura en recorrer dicha distancia. (p. 72)

B

- balanced chemical equation:** chemical equation with the same number of atoms of each element on both sides of the equation. (p. 726)
- balanced forces:** forces on a object that combine to give a zero net force and do not change the motion of the object. (p. 82)
- ☀ **base:** any substance that forms hydroxide ions, OH^- , in a water solution. (p. 766)
- beta particle:** electron that is emitted from a decaying atomic nucleus. (p. 793)
- bias:** occurs when a scientist's expectations change how the results of an experiment are viewed. (p. 10)
- big bang theory:** the theory that the universe started with a big bang, or explosion, and has been expanding ever since. (p. 837)
- binary compound:** compound that is composed of two elements. (p. 703)
- biomass:** renewable organic matter from plants and animals, such as wood and animal manure, that can be burned to provide heat. (p. 506)

- ecuación química balanceada:** ecuación química con el mismo número de átomos de cada elemento en los dos lados de la ecuación. (p. 726)
- fuerzas equilibradas:** fuerzas en un objeto que se combinan para dar una fuerza neta de cero y no cambiar el movimiento del objeto. (p. 82)
- base:** sustancia que forma iones de hidróxido, OH^- , en una solución de agua. (p. 766)
- partícula beta:** electrón emitido por un núcleo atómico en descomposición. (p. 793)
- predisposición:** ocurre cuando las expectativas de un científico cambian la forma en que son vistos los resultados de un experimento. (p. 10)
- teoría de la gran explosión:** teoría que explica que el universo comenzó con una gran explosión y que se ha estado expandiendo desde entonces. (p. 837)
- compuesto binario:** compuesto conformado por dos elementos. (p. 703)
- biomasa:** materia orgánica renovable proveniente de plantas y animales, tales como madera y estiércol animal, que puede ser incinerada para producir calor. (p. 506)

biosphere/chemical reaction

biosphere: everything organic, including plants, animals, and humans. (p. 529)

bubble chamber: radiation detector, consisting of a container of superheated liquid under high pressure, that is used to detect the paths of charged particles. (p. 797)

biosfera/reacción química

biosfera: cualquier entidad orgánica, incluyendo plantas, animales y humanos. (p. 529)

cámara de burbujas: detector de radiación que consiste de un contenedor de un líquido sobrecalentado a alta presión, usado para detectar la trayectoria de las partículas cargadas. (p. 797)

C

carrier wave: specific frequency that a radio station is assigned and uses to broadcast signals. (p. 469)

☀ **catalyst:** substance that speeds up a chemical reaction without being permanently changed itself. (p. 740)

cathode-ray tube: sealed vacuum tube that produces one or more beams of electrons that produce an image when they strike the coating on the inside of a TV screen. (p. 472)

cementation: sedimentary rock-forming process in which minerals precipitate out of water and fill the spaces between clasts. (p. 625)

centripetal acceleration: acceleration of an object toward the center of a curved or circular path. (p. 110)

☀ **centripetal force:** a net force that is directed toward the center of a curved or circular path. (p. 110)

chain reaction: ongoing series of fission reactions. (p. 802)

charging by contact: process of transferring charge between objects by touching or rubbing. (p. 395)

charging by induction: process of rearranging electrons on a neutral object by bringing a charged object close to it. (p. 396)

chemical bond: force that holds atoms together in a compound. (p. 694)

chemical change: change of one substance into a new substance. (p. 564)

chemical equation: shorthand method to describe chemical reactions using chemical formulas and other symbols. (p. 723)

chemical formula: chemical shorthand that uses symbols to tell what elements are in a compound and their ratios. (p. 689)

chemical potential energy: energy stored in chemical bonds. (p. 131)

chemical property: any characteristic of a substance, such as flammability, that indicates whether it can undergo a certain chemical change. (p. 563)

chemical reaction: process in which one or more substances are changed into new substances. (p. 720)

onda transportadora: frecuencia específica que se le asigna a una estación de radio y que la usa para emitir señales. (p. 469)

catalizador: sustancia que acelera una reacción química sin cambiar el mismo permanentemente. (p. 740)

tubo de rayos catódicos: tubo vacío sellado que produce uno o más haces de electrones para producir una imagen al chocar con el revestimiento del interior de una pantalla de televisor. (p. 472)

cementación: proceso de formación de rocas sedimentarias en el que los minerales se precipitan del agua y rellenan los espacios entre los clastos. (p. 625)

aceleración centrípeta: aceleración de un objeto dirigida hacia el centro de un trayecto curvo o circular. (p. 110)

fuerza centrípeta: fuerza neta dirigida hacia el centro de un trayecto curvo o circular. (p. 110)

reacción en cadena: serie continua de reacciones de fisión. (p. 802)

carga por contacto: proceso de transferir carga entre objetos por contacto o fricción. (p. 395)

carga por inducción: proceso de redistribución de los electrones en un objeto neutro acercándoles un objeto con carga. (p. 396)

enlace químico: fuerza que mantiene a los átomos juntos dentro de un compuesto. (p. 694)

cambio químico: transformación de una sustancia en una nueva sustancia. (p. 564)

ecuación química: método simplificado para describir reacciones químicas usando fórmulas químicas y otros símbolos. (p. 723)

fórmula química: nomenclatura química que usa símbolos para expresar qué elementos están en un compuesto y en qué proporción. (p. 689)

energía química potencial: energía almacenada en los enlaces químicos. (p. 131)

propiedad química: cualquier característica de una sustancia, como por ejemplo la combustibilidad, que indique si puede someterse a determinado cambio químico. (p. 563)

reacción química: proceso en el cual una o más sustancias son cambiadas por nuevas sustancias. (p. 720)

Glossary/Glosario

cinder cone volcano/concave mirror

cinder cone volcano: small, violently erupting volcano formed by accumulation of large pyroclastic materials around a vent. (p. 377)

circuit: closed conducting loop through which an electric current can flow. (p. 401)

clasts: bits and pieces of rock that vary widely in size and composition, are broken down by weathering, and may become consolidated into sedimentary rock. (p. 624)

cleavage: physical property of a mineral that causes it to break along planes that cut across relatively weak chemical bonds, creating a well-defined, smooth, flat surface. (p. 610)

cloud chamber: radiation detector that uses water or ethanol vapor to detect the paths of charged particles. (p. 796)

colloid (KAHL oyd): heterogeneous mixture whose particles never settle. (p. 556)

combustion reaction: a type of chemical reaction that occurs when a substance reacts with oxygen to produce energy in the form of heat and light. (p. 730)

comet: mass of dust, rock particles, frozen water, methane, and ammonia that travels through space and develops a bright, distinctive tail of light as it approaches the Sun and is pushed on by the solar wind. (p. 236)

composite volcano: large volcano formed by alternating lava flows and violently erupting pyroclastic materials. (p. 378)

★ **compound:** substance formed from two or more elements in which the exact combination and proportion of elements is always the same. (p. 554)

compound machine: machine that is a combination of two or more simple machines. (p. 174)

compressional wave: a wave for which the matter in the medium moves back and forth along the direction that the wave travels. (p. 290)

computer simulation: performance-testing method using a computer to imitate the process or procedure or to gather data. (p. 55)

concave lens: a lens that is thicker at the edges than in the middle; causes light rays to diverge and forms reduced, upright, virtual images; usually used in combination with other lenses. (p. 335)

concave mirror: a reflective surface that curves inward and can magnify objects or create beams of light. (p. 332)

volcán de cono de ceniza/espejo cóncavo

volcán de cono de ceniza: volcán pequeño, de erupción violenta formado por la acumulación de materiales piroclásticos grandes alrededor de una chimenea. (p. 377)

circuito: circuito conductor cerrado a través del cual puede fluir una corriente eléctrica. (p. 401)

clastos: toda clase de objetos rocosos que varían ampliamente en tamaño y composición, son degradados por el clima y pueden consolidarse en rocas sedimentarias. (p. 624)

clivaje: propiedad física de un mineral que causa que éste se rompa en planos que toman el camino más corto entre los enlaces químicos relativamente débiles, creando una superficie bien definida, suave y plana. (p. 610)

cámara de vapor: detector de radiaciones que usa vapor de agua o de etanol para detectar la trayectoria de las partículas cargadas. (p. 796)

coloide: mezcla heterogénea cuyas partículas nunca se sedimentan. (p. 556)

reacción de combustión: un tipo de reacción química que ocurre cuando una sustancia reacciona con oxígeno para producir energía en forma de calor y luz. (p. 730)

cometa: masa de polvo, partículas de roca, agua congelada, metano y amoníaco que viaja a través del espacio; desarrolla una cauda de luz brillante y distintiva a medida que se acerca al sol, y es empujada por vientos solares. (p. 236)

volcán compuesto: volcán grande formado por flujos alternantes de lava y materiales piroclásticos erupcionados violentamente. (p. 378)

compuesto: sustancia formada por dos o más elementos en la que la combinación y proporción exacta de los elementos es siempre la misma. (p. 554)

máquina compuesta: máquina compuesta por dos o más máquinas simples. (p. 174)

onda de compresión: onda para la cual la materia en el medio se mueve hacia adelante y hacia atrás en la dirección en que viaja la onda. (p. 290)

simulación computarizada: método de prueba del desempeño utilizando una computadora para imitar el proceso o procedimiento o para recopilar datos. (p. 55)

lente cóncavo: lente que es más delgado en los bordes que en el centro; hace que los rayos de luz se desvíen y forma imágenes reducidas, verticales y virtuales, generalmente utiliza en combinación con otros lentes. (p. 335)

espejo cóncavo: superficie reflexiva que se curva hacia el interior y que puede amplificar los objetos o crear rayos de luz. (p. 332)

concentration/critical mass

☀ **concentration:** how much solute is present in a solution compared to the amount of solvent. (p. 706)

conduction: transfer of thermal energy by collisions between particles in matter at a higher temperature and particles in matter at a lower temperature. (p. 266)

conductor: material, such as copper wire, in which electrons can move easily. (p. 395)

constant: in an experiment, a variable that does not change when other variables change. (p. 9)

constellation: star pattern that appears to form images, is used by astronomers to locate and name stars, and often is named for a mythological figure. (p. 818)

constraints: design limitations placed on products by outside factors, such as available materials, cost, and environmental impact. (p. 55)

continental climate: climate with little direct ocean influence and steep temperature gradients. (p. 532)

control: standard used for comparison of test results in an experiment. (p. 9)

control system: device or collection of devices used to monitor a system and limit system failures. (p. 56)

convection: transfer of thermal energy in a fluid from one place to another. (p. 267)

☀ **convergent boundary:** plate tectonic boundary where lithospheric plates collide. (p. 539)

convex lens: a lens that is thicker in the middle than at the edges and can form real or virtual images. (p. 333)

convex mirror: a reflective surface that curves outward and forms a reduced, upright, virtual image. (p. 333)

cosmology: study of how the universe began, what it is made of, and how it continues to evolve. (p. 836)

☀ **covalent bond:** attraction formed between atoms when they share electrons. (p. 697)

crest: the highest points on a transverse wave. (p. 294)

critical mass: amount of fissionable material required so that each fission reaction produces approximately one more fission reaction. (p. 802)

concentración/masa crítica

concentración: cantidad de soluto que está presente en una solución en comparación con la cantidad de solvente. (p. 706)

conducción: transferencia de energía térmica por colisiones entre partículas de materia a una temperatura alta y partículas de materia a una temperatura más baja. (p. 266)

conductor: material, como el alambre de cobre, a través del cual los electrones se pueden mover con facilidad. (p. 395)

constante: en un experimento, una variable que no cambia cuando cambian otras variables. (p. 9)

constelación: patrón estelar que parece formar imágenes; es usado por los astrónomos para ubicar y nombrar las estrellas, y con frecuencia se denomina con base en una figura mitológica (p. 818)

restricciones: limitaciones de diseño impuestas en los productos por factores externos, como los materiales disponibles, el costo y el impacto ambiental. (p. 55)

clima continental: clima con una pequeña influencia oceánica directa y gradientes abruptos de temperatura. (p. 532)

control: estándar usado para la comparación de resultados de pruebas en un experimento. (p. 9)

sistema de control: dispositivo o conjunto de dispositivos utilizados para monitorear un sistema y limitar sus fallas. (p. 56)

convección: transferencia de energía térmica en un fluido de un lugar a otro. (p. 267)

límite convergente: límite de la placa tectónica donde las placas litosféricas colisionan. (p. 539)

lente convexo: lente que es más delgado en el centro que en los bordes y que puede formar imágenes reales o virtuales. (p. 333)

espejo convexo: una superficie reflexiva que se curva hacia el exterior y forma una imagen reducida, vertical y virtual. (p. 333)

cosmología: estudio del origen del universo, de su composición y de la forma como continúa evolucionando. (p. 836)

enlace covalente: atracción formada entre átomos que comparten electrones. (p. 697)

cresta: los puntos más altos en una onda transversal. (p. 294)

masa crítica: cantidad de material fisiónable requerido de manera que cada reacción de fisión produzca aproximadamente una reacción de fisión adicional. (p. 802)

D

dark energy: energy that might be causing accelerated expansion of the universe. (p. 837)

dark matter: unseen mass that adds to the gravity of a galaxy, but cannot be detected or seen. (p. 838)

decibel: unit for sound intensity; abbreviated dB. (p. 322)

decomposition reaction: chemical reaction in which one substance breaks down into two or more substances. (p. 731)

density: mass per unit volume of a material. (p. 19)

dependent variable: factor that changes as a result of changes in the other variables. (p. 9)

deposition: process in which eroded materials are dropped by their transporting agents. (p. 654)

★ **diffraction:** the bending of waves around an obstacle; can also occur when waves pass through a narrow opening. (p. 304)

direct current (DC): electric current that flows in only one direction. (p. 442)

discontinuity: boundary marking an abrupt density change between Earth's layers. (p. 371)

displacement: distance and direction of an object's change in position from the starting point. (p. 71)

distance: how far an object moves. (p. 71)

distillation: process that can separate two substances in a mixture by evaporating a liquid and recondensing its vapor. (p. 563)

divergent boundary: plate tectonic boundary where lithospheric plates are moving apart. (p. 358)

Doppler effect: change in pitch or frequency that occurs when a source of a sound is moving relative to a listener. (p. 330)

double-displacement reaction: chemical reaction that produces a precipitate, water, or a gas when two ionic compounds in solution are combined. (p. 732)

drainage basin: land area that gathers water for a major river. (p. 655)

energía oscura: energía que podría estar causando la expansión acelerada del universo. (p. 837)

materia oscura: masa no vista que se suma a la gravedad de una galaxia pero que no puede detectarse o verse. (p. 838)

decibel: unidad que mide la intensidad del sonido; se abrevia dB. (p. 322)

reacción de descomposición: reacción química en la cual una sustancia se descompone en dos o más sustancias. (p. 731)

densidad: masa por unidad de volumen de un material. (p. 19)

variable dependiente: factor que varía como resultado de los cambios en las otras variables. (p. 9)

deposición: proceso en el que los materiales erosionados son decantados a partir de sus agentes transportadores. (p. 654)

difracción: curvatura de las ondas alrededor de un obstáculo, la cual también puede ocurrir cuando éstas pasan a través de una abertura angosta. (p. 304)

corriente directa (CD): corriente eléctrica que fluye en una sola dirección. (p. 442)

discontinuidad: límite que marca un cambio abrupto de densidad entre las capas de la Tierra. (p. 371)

desplazamiento: distancia y dirección del cambio de posición de un objeto desde el punto inicial. (p. 71)

distancia: qué tan lejos se mueve un objeto. (p. 71)

destilación: proceso que puede separar dos sustancias de una mezcla por medio de la evaporación de un líquido y la recondensación de su vapor. (p. 563)

límite divergente: límite de las placas tectónicas donde las placas litosféricas se alejan. (p. 358)

efecto Doppler: cambio en la altura o frecuencia que ocurre cuando una fuente de sonido se mueve en relación con un oyente. (p. 330)

reacción de doble desplazamiento: reacción química que produce un precipitado, agua o gas cuando se combinan dos compuestos iónicos en una solución. (p. 732)

cuenca de drenaje: área terrestre que capta agua para un río grande. (p. 655)

E

Earth: third planet from the Sun; the only planet known to support life and to have water on its surface as a gas, a liquid, and a solid. (p. 225)

tierra: tercer planeta más cercano al ; el único planeta que se sabe que alberga vida y que tiene agua en su superficie en estado sólido, líquido y gaseoso. (p. 225)

ecliptic/El Niño

ecliptic: yearly path of Earth around the Sun; also, the Sun's apparent path through the zodiac. (p. 192)

efficiency: ratio of the output work done by the machine to the input work done on the machine, expressed as a percentage. (p. 164)

elastic potential energy: energy stored when an object is compressed or stretched. (p. 131)

elastic rebound: sudden energy release that accompanies fault movement and causes earthquakes, or seismic vibrations. (p. 363)

electric current: the net movement of electric charges in a single direction, measured in amperes (A). (p. 400)

electric motor: device that converts electrical energy to mechanical energy by using the magnetic forces between an electromagnet and a permanent magnet to make a shaft rotate. (p. 435)

electric power: rate at which electrical energy is converted to another form of energy; expressed in watts (W). (p. 410)

✱ **electromagnet:** temporary magnet made by wrapping a wire coil, carrying a current, around an iron core. (p. 432)

electromagnetic induction: process in which electric current is produced in a wire loop by a changing magnetic field. (p. 438)

✱ **electromagnetic waves:** waves created by vibrating electric charges, can travel through a vacuum or through matter, and have a wide variety of frequencies and wavelengths. (p. 456)

electron cloud: area around the nucleus of an atom where the atom's electrons are most likely to be found. (p. 583)

electron dot diagram: uses the symbol for an element and dots representing the number of electrons in the element's outer energy level. (p. 594)

electrons: particles surrounding the center of an atom that have a charge of $1-$. (p. 579)

element: substance with atoms that are all alike. (p. 552)

ellipse: elongated, closed curve with two foci; shape of Earth's orbit around the Sun. (p. 188)

El Niño: a warming of the Pacific Ocean every three to five years, which dramatically alters worldwide weather patterns, and occurs when prevailing trade winds weaken near the equator. (p. 539)

eclíptico/El Niño

eclíptico: trayectoria anual de la tierra alrededor del Sol; también, la trayectoria aparente del Sol a través del zodíaco. (p. 192)

eficiencia: relación del trabajo efectuado por una máquina y el trabajo hecho en ésta, expresada en porcentaje. (p. 164)

energía elástica potencial: energía almacenada cuando un objeto es comprimido o estirado. (p. 131)

rebote elástico: liberación súbita de energía que acompaña al movimiento de las fallas y que causa terremotos o vibraciones sísmicas. (p. 363)

corriente eléctrica: movimiento neto de cargas eléctricas en una sola dirección, medido en amperios (A). (p. 400)

motor eléctrico: dispositivo que convierte la energía eléctrica en energía mecánica usando las fuerzas magnéticas entre un electroimán y un imán permanente para que el eje gire. (p. 435)

potencia eléctrica: proporción a la cual la energía eléctrica se convierte en otra forma de energía; se expresa en vatios (V). (p. 410)

electroimán: imán temporal que se hace envolviendo una bobina de cable que conduce una corriente, alrededor de un núcleo de hierro. (p. 432)

inducción electromagnética: proceso en el cual una corriente eléctrica es producida en un circuito cerrado de cable mediante un campo magnético cambiante. (p. 438)

ondas electromagnéticas: ondas creadas por la vibración de cargas eléctricas, que pueden viajar a través del vacío o de la materia y que tienen una amplia variedad de frecuencias y de longitudes de onda. (p. 456)

nube de electrones: área alrededor del núcleo de un átomo en donde hay más probabilidad de encontrar los electrones de los átomos. (p. 583)

diagrama de punto de electrones: usa el símbolo de un elemento y puntos que representan el número de electrones en el nivel de energía externo del elemento. (p. 594)

electrones: partículas que rodean el centro de un átomo que tienen la carga de $1-$. (p. 579)

elemento: sustancia en la cual todos los átomos son iguales. (p. 552)

elipse: curva alargada y cerrada con dos distancias focales; forma de la órbita terrestre alrededor del Sol. (p. 188)

El Niño: calentamiento del Océano Pacífico cada tres a cinco años, el cual altera dramáticamente los patrones climáticos en todo del mundo y que ocurre cuando los vientos alisios se debilitan cerca del ecuador. (p. 539)

Glossary/Glosario

endothermic reaction/foliated

- endothermic reaction:** chemical reaction that requires heat energy in order to proceed. (p. 735)
- energy:** the ability to do work and cause a change to occur. (p. 128)
- engineer:** researcher who uses scientific information or ideas to solve problems or human needs and bring technology to consumers. (p. 53)
- entropy:** a measure of how spread out, or dispersed energy is. (p. 276)
- epicenter:** point on Earth's surface directly above an earthquake's focus. (p. 364)
- equinox:** occurs twice yearly (March and September), when the Sun is directly above Earth's equator, and the number of daylight hours equals the number of nighttime hours worldwide. (p. 195)
- erosion:** removal of surface material through weathering by agents such as wind and water. (p. 654)
- exothermic reaction:** chemical reaction in which energy is primarily given off in the form of heat. (p. 738)
- experiment:** organized procedure for testing a hypothesis; tests the effect of one thing on another under controlled conditions. (p. 8)
- extrasolar planet:** planet in orbit around another star. (p. 222)
- extraterrestrial life:** life on other worlds. (p. 239)
- extrusive igneous rock:** rock formed from rapidly cooling lava that has erupted at Earth's surface or formed from consolidated solid materials expelled from volcanoes. (p. 620)

reacción endotérmica/foliado

- reacción endotérmica:** reacción química que requiere energía de calor para proceder. (p. 735)
- energía:** capacidad de realizar un trabajo y hacer que ocurra un cambio. (p. 128)
- ingeniero:** investigador que utiliza información científica o ideas para solucionar problemas o necesidades humanas y brindar tecnología a los consumidores. (p. 53)
- entropía:** una medida del grado de diseminación o dispersión de la energía. (p. 276)
- epicentro:** punto de la superficie terrestre directamente encima del foco de un terremoto. (p. 364)
- equinoccio:** fenómeno que ocurre dos veces al año (marzo y septiembre), cuando el Sol está directamente sobre el ecuador terrestre y en el que el número de horas en el día es igual al número de horas en la noche en todo el mundo. (p. 195)
- erosión:** remoción del material superficial a través del desgaste por agentes como el viento y el agua. (p. 654)
- reacción exotérmica:** reacción química en la cual la energía es inicialmente emitida en forma de calor. (p. 738)
- experimento:** procedimiento organizado para probar una hipótesis; prueba el efecto de una cosa sobre otra bajo condiciones controladas. (p. 8)
- planeta extrasolar:** planeta en órbita alrededor de otra estrella. (p. 222)
- vida extraterrestre:** vida en otros mundos. (p. 239)
- roca ígnea extrusiva:** roca formada a partir de lava que fue erupcionada a la superficie terrestre y que se enfrió rápidamente o formada a partir de materiales sólidos consolidados expulsados de los volcanes. (p. 620)

F

- ✱ **fault:** crack in Earth's crust along which movement has taken place. (p. 364)
- first law of motion:** states that if the net force on an object is zero, then an object at rest remains at rest, or, if the object is moving, it continues moving with constant velocity. (p. 98)
- ✱ **first law of thermodynamics:** states that the increase in thermal energy of a system equals the work done on the system plus the heat added to the system. (p. 274)
- focus:** point of origin of an earthquake. (p. 363)
- foliated:** type of metamorphic rock whose grains are arranged in layers or bands. (p. 631)

- falla:** fisura en la corteza terrestre a lo largo de la cual ha tenido lugar un movimiento. (p. 364)
- primera ley del movimiento:** ley que establece que si la fuerza neta sobre un objeto es cero, entonces un objeto en reposo permanece en reposo, o, si el objeto está moviéndose, éste continúa moviéndose con una velocidad constante. (p. 98)
- primera ley de la termodinámica:** establece que el aumento en la energía térmica de un sistema es igual al trabajo realizado sobre el sistema más el calor agregado a éste. (p. 274)
- foco:** punto de origen de un terremoto. (p. 363)
- foliado:** tipo de roca metamórfica cuyos granos están dispuestos en capas o bandas. (p. 631)

force/Global Positioning System (GPS)

force: a push or pull exerted on an object. (p. 81)

fossil fuels: oil, natural gas, and coal; formed from the decayed remains of ancient plants and animals. (p. 487)

fossils: remains or traces of organisms found in the geologic rock record; can be direct remains such as bones, mold and cast formations, and trace impressions. (p. 671)

fracture: physical property of a mineral that causes it to break into uneven pieces. (p. 610)

frequency: the number of wavelengths that pass a fixed point each second; expressed in hertz (Hz). (p. 295)

friction: a force that opposes the sliding motion between objects that are in contact. (p. 83)

fuerza/Sistema de Posicionamiento Global (GPS)

fuerza: impulso o tracción sobre un objeto. (p. 81)

combustibles fósiles: petróleo, gas natural y carbón formados por los restos descompuestos de plantas y animales ancestrales. (p. 487)

fósiles: restos o vestigios de organismos que se encuentran en el registro geológico; pueden ser restos directos como huesos, moldes, impresiones fosilizadas e impresiones de huellas. (p. 671)

fractura: propiedad física de un mineral que causa que éste se rompa en piezas asimétricas. (p. 610)

frecuencia: el número de longitudes de onda que pasan por un punto fijo en un segundo; expresa en hertz (Hz). (p. 295)

fricción: una fuerza que se opone al movimiento deslizante entre los objetos que están en contacto. (p. 83)

G

galaxy: large group of stars, gas, and dust held together by gravity; most commonly can be elliptical, spiral, and irregular. (p. 831)

galvanometer: a device that uses an electromagnet to measure electric current. (p. 434)

gamma ray: electromagnetic wave with no mass and no charge that travels at the speed of light and is usually emitted with alpha or beta particles from a decaying atomic nucleus; has a wavelength less than about ten trillionths of a meter. (pp. 467, 793)

Geiger counter: radiation detector that produces a click or a flash of light when a charged particle is detected. (p. 798)

generator: device that uses electromagnetic induction to convert mechanical energy to electrical energy. (p. 400)

geocentric model: Earth-centered model of the solar system. (p. 218)

geothermal energy: thermal energy in hot magma; can be converted by a power plant into electrical energy. (p. 505)

giant: late stage in a star's life cycle that occurs when its hydrogen fuel is depleted, its core contracts, and its outer layers expand and cool. (p. 825)

Global Positioning System (GPS): a system of satellites and ground monitoring stations that enable a receiver to determine its location at or above Earth's surface. (p. 475)

galaxia: grupo grande de estrellas, gas y polvo mantenidos juntos por la gravedad; comúnmente pueden ser elípticas, espirales e irregulares. (p. 831)

galvanómetro: dispositivo que usa un electroimán para medir la corriente eléctrica. (p. 434)

rayo gama: onda electromagnética sin masa ni carga que viaja a la velocidad de la luz y que usualmente es emitida con partículas alfa o beta a partir de un núcleo atómico en descomposición; tiene una electromagnética con longitudes de onda menores a diez trillonésimas de metro. (pp. 467, 793)

contador Geiger: detector de radiación que produce un sonido seco o un destello de luz al detectar una partícula cargada. (p. 798)

generador: dispositivo que usa inducción electromagnética para convertir energía mecánica en energía eléctrica. (p. 400)

modelo geocéntrico: modelo del sistema solar centrado en la tierra. (p. 218)

energía geotérmica: energía térmica en el magma caliente, la cual se puede convertir mediante una planta industrial en energía eléctrica. (p. 505)

gigante: última etapa en el ciclo de vida de una estrella que ocurre cuando su combustible hidrógeno es agotado, su núcleo se contrae y sus capas externas se expanden y enfrían. (p. 825)

Sistema de Posicionamiento Global (GPS): sistema de satélites y estaciones de monitoreo en tierra que permiten que un receptor determine su ubicación en o sobre la superficie terrestre. (p. 475)

Glossary/Glosario

global warming/hydrate

global warming: increased atmospheric heating from activities such as fossil fuel burning, which have increased air pollution and concentrations of trace gases and dust and modified the water and carbon cycles. (p. 538)

graph: visual display of information or data that can provide a quick way to communicate a lot of information and allow scientists to observe patterns. (p. 22)

gravitational potential energy: energy stored by objects due to their position above Earth's surface; depends on the distance above Earth's surface and the object's mass. (p. 132)

gravity: attractive force between two objects that depends on the masses of the objects and the distance between them. (p. 104)

greenhouse effect: atmospheric warming involving heat absorption by trace gases such as carbon dioxide and water vapor. (p. 520)

group: vertical column in the periodic table. (p. 592)

calentamiento global/hidrato

calentamiento global: aumento de la temperatura atmosférica por actividades como la quema de combustibles fósiles, lo cual incrementa la polución del aire y las concentraciones de gases traza y polvo y modifica los ciclos del agua y del carbono. (p. 538)

gráfica: presentación visual de información que puede suministrar una forma rápida de comunicar gran cantidad de información y que permite que los científicos puedan observar los patrones. (p. 22)

energía gravitacional potencial: energía almacenada por objetos debido a su posición sobre la superficie terrestre, la cual depende de la distancia sobre la superficie terrestre y de la masa del objeto. (p. 132)

gravedad: fuerza de atracción entre dos objetos que depende de las masas de los objetos y de la distancia entre ellos. (p. 104)

efecto de invernadero: calentamiento atmosférico que involucra la absorción de calor por gases traza como el dióxido de carbono y el vapor de agua. (p. 520)

grupo: columna vertical en la tabla periódica. (p. 592)

H

☼ **half-life:** amount of time it takes for half the nuclei in a sample of a radioactive isotope to decay. (p. 794)

hardness: physical property of a mineral that measures resistance to scratching. (p. 611)

heat: thermal energy that flows from a warmer material to a cooler material. (p. 257)

☼ **heat of fusion:** amount of energy required to change a substance from the solid phase to the liquid phase. (p. 262)

☼ **heat of vaporization:** the amount of energy required for the liquid at its boiling point to become a gas. (p. 262)

heliocentric model: Sun-centered model of the solar system. (p. 219)

heterogeneous (het uh ruh JEE nee us) mixture: mixture, such as mixed nuts or a dry soup mix, in which different materials are unevenly distributed and are easily identified. (p. 555)

homogeneous (hoh moh JEE nee us) mixture: solid, liquid, or gas that contains two or more substances blended evenly throughout. (p. 556)

hydrate: compound that has water chemically attached to its ions and written into its chemical formula. (p. 708)

vida media: tiempo requerido para que se descomponga la mitad de los núcleos de una muestra de isótopo radiactivo. (p. 794)

dureza: propiedad física de un mineral que mide la resistencia al desgaste. (p. 611)

calor: energía térmica que fluye de un material caliente a uno frío. (p. 257)

calor de fusión: cantidad de energía necesaria para cambiar una sustancia del estado sólido al líquido. (p. 262)

calor de vaporización: cantidad de energía necesaria para que un líquido en su punto de ebullición se convierta en gas. (p. 262)

modelo heliocéntrico: modelo del sistema solar centrado en el sol. (p. 219)

mezcla heterogénea: mezcla, tal como una mezcla de nueces o una mezcla seca para hacer sopa, en la cual diferentes materiales están distribuidos en forma desigual y se pueden identificar fácilmente. (p. 555)

mezcla homogénea: sólido, líquido, o gas que contiene dos o más sustancias mezcladas de manera uniforme en toda la mezcla. (p. 556)

hidrato: compuesto que contiene agua químicamente conectada a sus iones y representada en su fórmula química. (p. 708)

hydroelectricity/intrusive igneous rock

hydroelectricity: electricity produced from the energy of falling water. (p. 503)

hypothesis: educated guess using what you know and what you observe. (p. 8)

inclined plane: simple machine that consists of a sloping surface, such as a ramp, that reduces the amount of force needed to lift something by increasing the distance over which the force is applied. (p. 172)

independent variable: factor that, as it changes, affects the measure of another variable. (p. 9)

index of refraction: property of a material indicating how much light slows down when traveling in the material. (p. 329)

✱ **indicator:** organic compound that changes color in acids and bases. (p. 764)

inertia: resistance of an object to a change in its motion. (p. 99)

infiltration: process by which water enters Earth to become groundwater, controlled by the slope of the land, type of surface material, and type and amount of vegetation. (p. 663)

infrared waves: electromagnetic waves that have a wavelength between about 1 mm and 750 billionths of a meter. (p. 464)

inhibitor: substance that slows down a chemical reaction or prevents it from occurring by combining with a reactant. (p. 740)

input force: force exerted on a machine. (p. 162)

instantaneous speed: speed of an object at a given point in time; is constant for an object moving with constant speed, and changes with time for an object that is slowing down or speeding up. (p. 71)

insulator: material in which electrons are not able to move easily. (p. 395); material in which heat flows slowly. (p. 270)

intensity: amount of energy that flows through a certain area in a specific amount of time. (p. 322)

interference: occurs when two or more waves overlap and combine to form a new wave. (p. 306)

internal combustion engine: heat engine that burns fuel inside the engine in chambers or cylinders. (p. 275)

intrusive igneous rock: coarse-grained rock formed from slowly cooling magma below Earth's surface. (p. 617)

hidroelectricidad/roca ígnea intrusiva

hidroelectricidad: electricidad producida a partir de la energía generada por una caída de agua. (p. 503)

hipótesis: suposición fundamentada que se basa en lo que se sabe y lo que se observa. (p. 8)

plano inclinado: máquina simple que consiste de una superficie inclinada, tal como una rampa, que reduce la fuerza necesaria para levantar un objeto aumentando la distancia sobre la cual se aplica dicha fuerza. (p. 172)

variable independiente: factor que, a medida que cambia, afecta la medida de otra variable. (p. 9)

índice de refracción: propiedad de un material para indicar la cantidad de luz que se frena al pasar a través del material. (p. 329)

indicador: compuesto orgánico que cambia de color en presencia de ácidos y bases. (p. 764)

inercia: resistencia de un objeto a cambiar su movimiento. (p. 99)

infiltración: proceso mediante el cual el agua entra en la tierra para convertirse en agua subterránea, controlado por la pendiente del suelo, el tipo de material superficial y el tipo y cantidad de vegetación. (p. 663)

ondas infrarrojas: ondas electromagnéticas que tienen una longitud de onda entre aproximadamente 1 mm y 750 billonésimas de metro. (p. 464)

inhibidor: sustancia que reduce una reacción química o previene que ocurra por una combinación con un reactivo. (p. 740)

fuerza de entrada: fuerza ejercida sobre una máquina. (p. 162)

velocidad instantánea: velocidad de un objeto en un punto dado en el tiempo; es constante para un objeto que se mueve a una velocidad constante y cambia con el tiempo en un objeto que está reduciendo o aumentando su velocidad. (p. 71)

aislador: material a través del cual los electrones no se pueden mover con facilidad. (p. 395); material en el cual el calor fluye lentamente. (p. 270)

intensidad: cantidad de energía que fluye a través de cierta área en un tiempo específico. (p. 322)

interferencia: ocurre cuando dos o más ondas se superponen y combinan para formar una nueva onda. (p. 306)

motor de combustión interna: motor de calor que quema combustible en su interior en cámaras o cilindros. (p. 275)

roca ígnea intrusiva: roca áspera y granulosa formada a partir de un enfriamiento lento del magma debajo de la superficie terrestre. (p. 617)

Glossary/Glosario

ion/law of conservation of mass

ion: charged particle that has either more or fewer electrons than protons. (pp. 692, 707)

ionic bond: attraction formed between oppositely charged ions in an ionic compound. (p. 696)

☀ **isotopes:** atoms of the same element that have different numbers of neutrons. (p. 586)

ion/ley de conservación de la masa

ion: partícula cargada que tiene ya sea más o menos electrones que protones. (pp. 692, 707)

enlace iónico: atracción formada entre iones con cargas opuestas en un compuesto iónico. (p. 696)

isótopos: átomos del mismo elemento que tienen diferente número de neutrones. (p. 586)

J

jet stream: high-speed, powerful air current that affects many weather processes, such as the development of storms. (p. 525)

joule: SI unit of energy. (p. 130)

Jupiter: largest and fifth planet from the Sun; has continuous, swirling, high-pressure gas storms, the largest of which is the Great Red Spot. (p. 231)

corriente a presión: corriente de aire poderosa y de alta velocidad que afecta a muchos procesos climáticos, como el desarrollo de las tormentas. (p. 525)

julio: unidad SI de energía. (p. 130)

Júpiter: quinto planeta más cercano al Sol, también es el más grande; tiene tormentas gaseosas arremolinadas y continuas de alta presión, la más grande de las cuales es la Gran Mancha Roja. (p. 231)

K

☀ **Kelvin:** the SI unit for temperature, abbreviated K; a temperature change of 1 Kelvin is the same as a temperature change of 1°C. (p. 255)

kinetic energy: energy a moving object has because of its motion; depends on the mass and speed of the object. (p. 130)

kinetic theory: explanation of the behavior of molecules in matter; states that all matter is made of constantly moving particles that collide without losing energy. (p. 254)

Kelvin: la unidad del sistema internacional de medidas para la temperatura, cuya abreviatura es K; un cambio en la temperatura de 1 grado kelvin es lo mismo que un cambio en la temperatura de 1°C. (p. 255)

energía cinética: energía que tiene un cuerpo debido a su movimiento, la cual depende de la masa y velocidad del objeto. (p. 130)

teoría cinética: explicación del comportamiento de las moléculas en la materia, la cual establece que todas las sustancias están compuestas de partículas en constante movimiento que colindan sin perder energía. (p. 254)

L

La Niña: climatic phenomenon that occurs when Pacific trade winds are very strong and temperatures colder than normal; the opposite of El Niño. (p. 539)

latent heat: energy used to melt snow or evaporate water. (p. 520)

law of conservation of charge: states that charge can be transferred from one object to another but cannot be created or destroyed. (p. 393)

law of conservation of energy: states that energy can never be created or destroyed. (p. 139)

law of conservation of mass: states that the mass of all substances present before a chemical change equals the mass of all the substances remaining after the change. (p. 567)

La Niña: fenómeno climático que ocurre cuando los vientos alisios del pacífico son muy fuertes y la temperatura disminuye más de lo normal; lo opuesto a El Niño. (p. 539)

calor latente: energía utilizada para derretir nieve o evaporar agua. (p. 520)

ley de la conservación de carga: establece que la carga puede ser transferida entre un objeto y otro pero no puede ser creada o destruida. (p. 393)

ley de la conservación de energía: establece que la energía nunca puede ser creada ni destruida. (p. 139)

ley de conservación de la masa: establece que la masa de todas las sustancias presente antes de un cambio químico es igual a la masa de todas las sustancias resultantes después del cambio. (p. 567)

law of conservation of momentum/maria

law of conservation of momentum: states that if a group of objects exerts forces only on each other, then the total momentum of the objects doesn't change (p. 117)

lee rain shadow: area of reduced precipitation on one side of a mountain range. (p. 533)

lever: simple machine consisting of a bar free to pivot about a fixed point called the fulcrum. (p. 166)

light-year: distance light travels in one year—about 9.5 billion km. (p. 820)

Local Group: cluster of about 45 galaxies, including the Milky Way. (p. 831)

longshore current: movement of water parallel to the shoreline caused by waves colliding with the shore at an angle, which results in net sediment transport parallel to the shoreline. (p. 659)

loudness: human perception of sound intensity. (p. 322)

lunar eclipse: occurs during full moon, when the Moon enters Earth's umbra and Earth casts a curved shadow on the Moon's surface. (p. 202)

ley de la conservación del movimiento/maría

ley de la conservación del movimiento: ley que establece que si en un grupo de objetos se ejercen fuerzas sólo en unos sobre otros, entonces el momento total de los objetos no cambia. (p. 117)

sombra lluviosa a sotavento: área de precipitación reducida en un lado de un sistema montañoso. (p. 533)

palanca: máquina simple que consiste de una barra que puede girar sobre un punto fijo llamado pivote. (p. 166)

año luz: distancia que viaja la luz en un año—cerca de 9 500 millones de km. (p. 820)

Grupo Local: agrupación de cerca de 45 galaxias, incluyendo la Vía Láctea. (p. 831)

corriente costera: movimiento de agua paralelo a la línea costera causado por olas que colisionan con la costa en ángulo, lo cual resulta en transporte neto de sedimentos paralelo a la línea costera. (p. 659)

volumen de sonido: percepción humana de la intensidad del sonido. (p. 322)

eclipse lunar: fenómeno que ocurre durante la luna llena, cuando la Luna entra en el cono de sombra de la Tierra y ésta proyecta una sombra curva sobre la superficie de la Luna. (p. 202)

M

machine: device that makes doing work easier by increasing the force applied to an object, changing the direction of an applied force, or increasing the distance over which a force can be applied. (p. 160)

magma: molten rock material found inside Earth. (p. 613)

magnetic domain: group of atoms in a magnetic material with the magnetic poles of the atoms pointing in the same direction. (p. 429)

magnetic field: surrounds a magnet and exerts a force on other magnets and objects made of magnetic materials. (p. 425)

magnetic pole: region on a magnet where the magnetic force exerted by a magnet is strongest; like poles repel and opposite poles attract. (p. 425)

magnetism: the properties and interactions of magnets. (p. 424)

main sequence: section of an H-R diagram that is plotted from the upper left to the lower right and contains 90 percent of all known stars. (p. 823)

maria: relatively flat, dark-colored regions on the Moon's surface. (p. 203)

máquina: artefacto que facilita la ejecución del trabajo aumentando la fuerza que se aplica a un objeto, cambiando la dirección de una fuerza aplicada o aumentando la distancia sobre la cual se puede aplicar una fuerza. (p. 160)

magma: material rocoso derretido que se encuentra en el interior de la Tierra. (p. 613)

dominio magnético: grupo de átomos en un material magnético en el cual los polos magnéticos de los átomos apuntan en la misma dirección. (p. 429)

campo magnético: rodea a un imán y ejerce una fuerza sobre otros imanes y objetos hechos de materiales magnéticos. (p. 425)

polo magnético: zona en un imán en donde la fuerza magnética ejercida por un imán es la más fuerte; los polos iguales se repelen y los polos opuestos se atraen. (p. 425)

magnetismo: propiedades e interacciones de los imanes. (p. 424)

secuencia principal: sección de un diagrama H-R que es graficado desde la parte superior izquierda hasta la parte inferior derecha y contiene el 90% de todas las estrellas conocidas. (p. 823)

maría: regiones relativamente planas y de color oscuro sobre la superficie de la luna. (p. 203)

Glossary/Glosario

maritime climate/moon phase

maritime climate: climate with a strong ocean influence and milder temperatures. (p. 532)

Mars: fourth planet from the Sun; called the red planet because of high concentrations of iron oxide. (p. 225)

mass: amount of matter in an object. (p. 19)

✱ **mass number:** sum of the number of protons and neutrons in an atom's nucleus. (p. 585)

mechanical advantage (MA): ratio of the output force exerted by a machine to the input force applied to the machine. (p. 164)

mechanical energy: sum of the potential energy and kinetic energy in a system. (p. 136)

medium: matter in which a wave travels. (p. 289)

Mercury: closest planet to the Sun; has a larger than expected iron core. (p. 223)

meteoroid: rocky solar system object formed from pieces of comets and asteroids. (pp. 236, 633)

microwaves: radio waves with wavelengths of between about 1 m and 1 mm. (p. 463)

✱ **mid-ocean ridge (MOR):** a continuous system of twin mountain ranges with a rift valley between them that extends around Earth on the seafloor; formed where two oceanic plates are forced apart due to magma rising from Earth's mantle; a source of new rock. (p. 356)

Milky Way: our spiral-shaped galaxy, which contains the solar system and about 400 billion stars, including the Sun, and measures about 100,000 light-years across. (p. 831)

mineral: naturally occurring, inorganic, crystalline solid with a predictable chemical composition and a characteristic set of physical properties. (p. 609)

model: can be used to represent an idea, object, or event that is too big, too small, too complex, or too dangerous to observe or test directly. (p. 11)

✱ **molecule:** a neutral particle that forms as a result of electron sharing. (p. 697)

✱ **momentum:** property of a moving object that equals its mass times its velocity. (p. 116)

moon phase: changing appearance of the Moon as viewed from Earth, depending on the relative positions of the Sun, the Moon, Earth, and the observer. (p. 199)

clima marítimo/fase lunar

clima marítimo: clima con una fuerte influencia oceánica y temperaturas templadas. (p. 532)

marte: cuarto planeta más cercano al Sol; llamado el planeta rojo debido a altas concentraciones de óxido de hierro. (p. 225)

masa: cantidad de materia en un objeto. (p. 19)

número de masa: suma del número de protones y neutrones en el núcleo de un átomo. (p. 585)

ventaja mecánica (MA): relación de la fuerza ejercida por una máquina y la fuerza aplicada a dicha máquina. (p. 164)

energía mecánica: suma de la energía potencial y energía cinética en un sistema. (p. 136)

medio: materia a través de la cual viaja una onda. (p. 289)

Mercurio: planeta más cercano al sol; tiene un núcleo de hierro más grande de lo esperado. (p. 223)

meteorito: objeto rocoso del sistema solar formado de pedazos de cometas y asteroides. (pp. 236, 633)

microondas: ondas de radio con longitudes de onda entre aproximadamente 1 mm y 1 m. (p. 463)

canto del mediados de-oceano (MOR): un sistema continuo de la montaña gemela se extiende con un valle de la grieta entre ellos que extienda alrededor de la tierra en el seafloor; formado donde están dos placas oceánicas separado forzado debido al magma que se levanta de la capa de la tierra; una fuente de la roca nueva. (p. 356)

Vía Láctea: nuestra galaxia en forma de espiral, la cual contiene al sistema solar y cerca de 400 000 millones de estrellas, incluyendo al Sol, y tiene una extensión de aproximadamente 100 000 años luz. (p. 831)

mineral: sólido de origen natural, inorgánico y cristalino con una composición química predecible y un conjunto característico de propiedades físicas. (p. 609)

modelo: puede ser usado para representar una idea, objeto o evento que es demasiado grande, demasiado pequeño, demasiado complejo o demasiado peligroso para ser observado o probado directamente. (p. 11)

molécula: partícula neutra que se forma al compartir electrones. (p. 697)

ímpetu: propiedad de un objeto en movimiento que es igual a su masa por su velocidad. (p. 116)

fase lunar: cambio en la apariencia de la Luna según es vista desde la Tierra, dependiendo de las posiciones relativas del Sol, la Luna, la Tierra y el observador. (p. 199)

N

Neptune: eighth planet from the Sun; has storms similar to Jupiter's and appears blue because of atmospheric methane. (p. 235)

net force: sum of the forces that are acting on an object. (p. 82)

neutron: neutral particle, composed of quarks, inside the nucleus of an atom. (p. 579)

nonpolar molecule: molecule that shares electrons equally and does not have oppositely charged ends. (p. 700)

nonrenewable resources: natural resource, such as fossil fuels, that cannot be replaced by natural processes as quickly as it is used. (p. 493)

✱ **nuclear fission:** process of splitting an atomic nucleus into two or more nuclei with smaller masses. (p. 801)

✱ **nuclear fusion:** reaction in which two or more atomic nuclei form a nucleus with a larger mass. (p. 803)

nuclear reactor: uses energy from a controlled nuclear chain reaction to generate electricity. (p. 494)

nuclear waste: radioactive by-product that results when radioactive materials are used. (p. 498)

nucleus: positively charged center of an atom that contains protons and neutrons and is surrounded by a cloud of electrons. (p. 579)

Neptuno: octavo planeta más cercano al Sol; tiene tormentas similares a las de Júpiter y parece azul debido al metano atmosférico. (p. 235)

fuerza neta: suma de fuerzas que actúan sobre un objeto. (p. 82)

neutrón: partícula neutra, compuesta por quarks, dentro del núcleo de un átomo. (p. 579)

molécula no polar: molécula que comparte equitativamente los electrones y que no tiene extremos con cargas opuestas. (p. 700)

recursos no renovables: recursos naturales, tales como combustibles fósiles, que no pueden ser reemplazados por procesos naturales tan pronto como son usados. (p. 493)

fisión nuclear: proceso de división de un núcleo atómico en dos o más núcleos con masas más pequeñas. (p. 801)

fusión nuclear: reacción en la cual dos o más núcleos atómicos forman un núcleo con mayor masa. (p. 803)

reactor nuclear: usa energía de una reacción nuclear controlada en cadena para generar electricidad. (p. 494)

desperdicio nuclear: subproducto radioactivo que resulta del uso de materiales radiactivos. (p. 498)

núcleo: centro de un átomo con carga positiva que contiene protones y neutrones y está rodeado por una nube de electrones. (p. 579)

O

Ohm's law: states that the current in a circuit equals the voltage difference divided by the resistance. (p. 405)

opaque: material that absorbs or reflects all light and does not transmit any light. (p. 327)

output force: force applied by a machine. (p. 162)

oxidation number: positive or negative number that indicates how many electrons an atom has gained, lost, or shared to become stable. (p. 703)

ley de Ohm: establece que la corriente en un circuito es igual a la diferencia de voltaje dividida por la resistencia. (p. 405)

opaco: material que absorbe o refleja toda la luz pero no la transmite. (p. 327)

fuerza de salida: fuerza aplicada por una máquina. (p. 162)

número de oxidación: número positivo o negativo que indica cuántos electrones ha ganado, perdido o compartido un átomo para poder ser estable. (p. 703)

P

parallel circuit: circuit in which electric current has more than one path to follow. (p. 406)

circuito paralelo: circuito en el cual la corriente eléctrica tiene más de una trayectoria para seguir. (p. 406)

period/polar molecule

period: the amount of time it takes one wavelength to pass a fixed point; expressed in seconds. (p. 295); horizontal row in the periodic table. (p. 595)

periodic table: organized list of all known elements that are arranged by increasing atomic number and by changes in chemical and physical properties. (p. 588)

☀ **permeability:** a measure of the ability of a fluid to pass through a material. (p. 665)

petroleum: liquid fossil fuel formed from decayed remains of ancient organisms; can be refined into fuels and used to make plastics. (p. 489)

☀ **pH:** a measure of the concentration of hydronium ions in a solution using a scale ranging from 0 to 14, with 0 being the most acidic and 14 being the most basic. (p. 773)

photon: particle that electromagnetic waves sometimes behave like; has energy that increases as the frequency of the electromagnetic wave increases. (p. 460)

photosphere: light-emitting surface of the Sun. (p. 827)

photovoltaic cell: device that converts solar energy into electricity; also called a solar cell. (p. 501)

physical change: any change in size, shape, or state of matter in which the identity of the substance remains the same. (p. 562)

physical property: any characteristic of a material, such as size or shape, that you can observe or attempt to observe without changing the identity of the material. (p. 560)

pigment: colored material that is used to change the color of other substances. (p. 342)

pilot plant: scaled-down version of real production equipment that closely models actual manufacturing conditions and is used to test a new manufacturing process. (p. 56)

pitch: how high or low a sound seems; related to the frequency of the sound waves. (p. 323)

plane mirror: flat, smooth mirror that reflects light to form upright, virtual images. (p. 331)

plasma: matter consisting of positively and negatively charged particles. (p. 261)

Pluto: smallest and ninth planet from the Sun; has a thin atmosphere and a solid, ice-rock surface. (p. 236)

polar molecule: molecule with a slightly positive end and a slightly negative end as a result of electrons being shared unequally. (p. 700)

período/molécula polar

período: la cantidad de tiempo que requiere una longitud de onda para pasar un punto fijo; expresa en segundos. (p. 295); fila horizontal en la tabla periódica. (p. 595)

tabla periódica: lista organizada de todos los elementos conocidos y que han sido ordenados de manera ascendente por número atómico y por cambios en sus propiedades químicas y físicas. (p. 588)

permeabilidad: medida de la capacidad de un fluido para pasar a través de un material. (p. 665)

petróleo: combustible fósil líquido que se forma a partir de residuos en descomposición de organismos ancestrales y que puede ser refinado para producir combustibles y usado para hacer plásticos. (p. 489)

pH: medida de la concentración de iones de hidronio en una solución, usando una escala de 0 a 14, en la cual 0 es la más ácida y 14 la más básica. (p. 773)

fotón: partícula como la cual algunas veces se comportan las ondas electromagnéticas; tiene energía que aumenta a medida que la frecuencia de la onda electromagnética aumenta. (p. 460)

fotosfera: superficie solar que emite luz. (p. 827)

células fotovoltaicas: dispositivo que convierte la energía solar en electricidad; también llamada celda solar. (p. 501)

cambio físico: cualquier cambio en tamaño, forma o estado de una sustancia en la cual la identidad de la sustancia sigue siendo la misma. (p. 562)

propiedad física: cualquier característica de un material, tal como tamaño o forma, que se puede haber observar o tratado de observar sin cambiar la identidad del material. (p. 560)

pigmento: material de color que se usa para cambiar el color de otras sustancias. (p. 342)

planta piloto: versión a escala reducida de un equipo de producción real que simula cercanamente las condiciones reales de fabricación y es utilizada para probar un proceso de fabricación nuevo. (p. 56)

altura: qué tan alto o bajo parece un sonido; tiene relación con la frecuencia de las ondas sonoras. (p. 323)

espejo plano: espejo plano y liso que refleja la luz para formar imágenes verticales y virtuales. (p. 331)

plasma: materia consistente de partículas con cargas positivas y negativas. (p. 261)

Plutón: noveno planeta y el más lejano al Sol, también el más pequeño; tiene una atmósfera delgada y una superficie sólida de hielo y roca. (p. 236)

molécula polar: molécula con un extremo ligeramente positivo y otro ligeramente negativo como resultado de un compartir desigual de los electrones. (p. 700)

polyatomic ion/radio waves

polyatomic ion: positively or negatively charged, covalently bonded group of atoms. (p. 707)

porosity: empty space in sedimentary rock in which water, oil, and natural gas are stored within Earth. (p. 625)

potential energy: stored energy an object has due to its position. (p. 131)

power: amount of work done, or the amount of energy transferred, divided by the time required to do the work or transfer the energy; measured in watts (W). (p. 157)

✱ **precision:** describes how closely measurements are to each other and how carefully the measurements were made. (p. 14)

principle of superposition: states that the oldest rocks in an undisturbed sequence of rocks are at the bottom of the undisturbed sequence. (p. 670)

✱ **product:** in a chemical reaction, the new substance that is formed. (p. 720)

proton: particle, composed of quarks, inside the nucleus of an atom that has a charge of 1+. (p. 579)

prototype: first full-scale model built to performance-test a new product. (p. 56)

pulley: simple machine that consists of a grooved wheel with a rope, chain, or cable running along the groove; can be either fixed or movable. (p. 169)

ion poliatómico/ondas de radio

ion poliatómico: grupo de átomos enlazados covalentemente, con carga positiva o negativa. (p. 707)

porosidad: espacio vacío en la roca sedimentaria en el que el agua, el petróleo y el gas natural son almacenados dentro de la Tierra. (p. 625)

energía potencial: energía almacenada que un objeto tiene debido a su posición. (p. 131)

potencia: cantidad de trabajo realizado o cantidad de energía transferida, dividida por el tiempo requerido para realizar el trabajo o transferir la energía; medida en vatios (V). (p. 157)

precisión: descripción de la cercanía de las mediciones una respecto a otra y del cuidado con el que se hacen éstas. (p. 14)

principio de superposición (estratigráfico): principio que establece que las rocas más antiguas en una secuencia de rocas sin perturbaciones están en la parte más baja de la secuencia no perturbada. (p. 670)

producto: es la nueva sustancia que se forma en una reacción química. (p. 720)

protón: partícula, compuesta por quarks, dentro del núcleo de un átomo que tiene una carga de 1+. (p. 579)

prototipo: el primer modelo a escala completa construido para probar el desempeño de un producto nuevo. (p. 56)

polea: máquina simple que consiste de una rueda acanalada con una cuerda, cadena o cable que se desliza por el canal y que puede ser fija o móvil. (p. 169)

Q

quarks: particles of matter that make up protons and neutrons. (p. 579)

quarks: partículas de materia que constituyen los protones y neutrones. (p. 579)

R

radiant energy: energy carried by an electromagnetic wave. (p. 459)

radiation: transfer of thermal energy by electromagnetic waves. (p. 269)

radioactivity: process that occurs when a nucleus decays and emits alpha, beta, or gamma radiation. (p. 788)

radio telescope: telescope that collects and magnifies radio waves. (p. 821)

radio waves: electromagnetic waves with wavelengths longer than about 1 mm, used for communications. (p. 463)

energía radiante: energía transportada por una onda electromagnética. (p. 459)

radiación: transferencia de energía térmica mediante ondas electromagnéticas. (p. 269)

radiactividad: proceso que ocurre cuando un núcleo se descompone y emite radiación alfa, beta o gama. (p. 788)

radio telescopio: telescopio que colecta y magnifica las ondas de radio. (p. 821)

ondas de radio: ondas electromagnéticas con longitudes de onda más largas de aproximadamente 1 mm y que se usan en las comunicaciones. (p. 463)

Glossary/Glosario

rarefaction/saturated solution

- rarefaction:** the least dense regions of a compressional wave. (p. 294)
- ★ **rate of reaction:** the speed at which reactants are consumed and products are produced in a given reaction. (p. 738)
- ★ **reactant:** in a chemical reaction, the substance that reacts. (p. 720)
- reflecting telescope:** optical instrument that uses a concave mirror to collect light and a lens to magnify an image. (p. 820)
- refracting telescope:** optical instrument that uses double convex lenses to collect light and magnify an image. (p. 819)
- refraction:** the bending of a wave as it changes speed in moving from one medium to another. (p. 302)
- regolith:** layer of debris on the Moon's surface formed by the accumulation of meteoric material. (p. 203)
- relative dating:** process of dating objects or events in time order, or sequence, based on logical relationships; may or may not involve the use of numbers. (p. 669)
- renewable resource:** energy source that is replaced almost as quickly as it is used. (p. 501)
- resistance:** tendency for a material to oppose electron flow and change electrical energy into thermal energy and light; measured in ohms (Ω). (p. 403)
- resonance:** the process by which an object is made to vibrate by absorbing energy at its natural frequencies. (p. 309)
- revolution:** movement of Earth in its orbit around the Sun; used to measure time in years. (p. 192)
- ★ **rift valley:** long, linear, dropped-down valley between twin, parallel mountain ranges produced by faulting. (p. 356)
- rock:** consolidated, natural mixture of minerals, volcanic glass, or rock fragments. (p. 617)
- rock cycle:** continuous process that forms and changes rocks on Earth's surface and deep below the surface. (p. 634)
- rotation:** spinning of Earth on its axis; used to measure time in days. (p. 192)

rarefacción/solución saturada

- rarefacción:** las regiones menos densas de una onda de compresión. (p. 294)
- fasa de reacción:** velocidad a la que los reactantes son consumidos y los productos son generados en una reacción dada. (p. 738)
- reactante:** es la sustancia que reacciona en una reacción química. (p. 720)
- telescopio de reflexión:** instrumento óptico que utiliza un espejo cóncavo para captar la luz y una lente para magnificar una imagen. (p. 820)
- telescopio de refracción:** instrumento óptico que utiliza lentes convexas dobles para captar la luz y magnificar una imagen. (p. 819)
- refracción:** curvatura de una onda al cambiar su velocidad al pasar de un medio a otro. (p. 302)
- regolito:** capa de escombros sobre la superficie lunar formada por la acumulación de material meteórico. (p. 203)
- datación relativa:** proceso de datar objetos o eventos en un orden o secuencia temporal, basado en relaciones lógicas; puede o no involucrar el uso de números. (p. 669)
- recursos renovables:** fuente de energía que es reemplazada casi tan pronto como es usada. (p. 501)
- resistencia:** tendencia de un material de oponerse al flujo de los electrones y convertir la energía eléctrica en energía térmica y luz; se mide en ohmios (Ω). (p. 403)
- resonancia:** el proceso por el cual un objeto vibra al absorber energía en sus frecuencias naturales. (p. 309)
- revolución:** movimiento de la Tierra en su órbita alrededor del sol, utilizado para medir el tiempo en años. (p. 192)
- valle de hendidura:** valle alargado, lineal y deprimido producido por una falla que se encuentra entre dos sistemas montañosos paralelos. (p. 356)
- roca:** mezcla natural y consolidada de minerales, obsidiana o fragmentos de roca. (p. 617)
- ciclo de la roca:** proceso continuo que forma y cambia las rocas sobre y debajo de la superficie terrestre. (p. 634)
- rotación:** giro de la Tierra sobre su eje, utilizado para medir el tiempo en días. (p. 192)

S

saturated solution: any solution that contains all the solute it can hold at a given temperature. (p. 761)

solución saturada: cualquier solución que contiene todo el soluto que puede retener a una temperatura determinada. (p. 761)

Saturn/society

Saturn: second-largest and sixth planet from the Sun; has the most complex system of rings. (p. 234)

scientific law: statement about what happens in nature that seems to be true all the time; does not explain why or how something happens. (p. 12)

scientific methods: organized set of investigation procedures that can include stating a problem, forming a hypothesis, researching and gathering information, testing a hypothesis, analyzing data, and drawing conclusions. (p. 7)

screw: simple machine that consists of an inclined plane wrapped in a spiral around a cylindrical post. (p. 173)

sea breeze: cooling breeze that blows from the sea toward land during the afternoon. (p. 533)

second law of motion: states that the acceleration of an object is in the same direction as the net force on the object, and that the acceleration equals the net force divided by the mass. (p. 102)

☀ **second law of thermodynamics:** states that is impossible for heat to flow from a cool object to a warmer object unless work is done. (p. 274)

sediment transport: movement of eroded materials by wind, water, and/or glaciers from one location to another. (p. 654)

Sedna: unofficial name for object 2003 VB12, a distant planetoid with a very elliptical orbit. (p. 237)

series circuit: circuit in which electric current has only one path to follow. (p. 407)

shadow zone: “dead zone” between 105 and 140 degrees from an earthquake’s epicenter, where nothing is recorded on a seismogram. (p. 371)

shield volcano: broad, flat volcano formed by layers of free-flowing, high-temperature, basaltic lava. (p. 377)

simple machine: machine that does work with only one movement—lever, pulley, wheel and axle, inclined plane, screw, and wedge. (p. 166)

single-displacement reaction: chemical reaction in which one element replaces another element in a compound. (p. 731)

sliding friction: frictional force that opposes the motion of two surfaces sliding past each other. (p. 84)

society: group of people who share similar values and beliefs. (p. 46)

Saturno/sociedad

Saturno: sexto planeta más cercano al Sol, también el segundo más grande; tiene el sistema de anillos más complejo. (p. 234)

ley científica: enunciado acerca de lo que ocurre en la naturaleza, lo cual parece ser cierto en todo momento, sin explicar cómo o por qué algo ocurre. (p. 12)

métodos científico: conjunto organizado de procedimientos de investigación que puede incluir el planteamiento de un problema, formulación de una hipótesis, investigación y recopilación de información, comprobación de la hipótesis, análisis de datos y elaboración de conclusiones. (p. 7)

tornillo: máquina simple que consiste de un plano inclinado envuelto en espiral alrededor de un poste cilíndrico. (p. 173)

brisa marina: brisa refrescante que sopla del mar hacia la tierra durante la tarde. (p. 533)

segunda ley de movimiento: establece que la aceleración de un objeto es en la misma dirección que la fuerza neta del objeto y que la aceleración es igual a la fuerza neta dividida por su masa. (p. 102)

segunda ley de la termodinámica: establece que es imposible que el calor fluya de un objeto frío a uno caliente, a menos que se realice un trabajo. (p. 274)

transporte de sedimentos: movimiento de materiales erosionados por el viento, agua o glaciares de un lugar a otro. (p. 654)

Sedna: nombre no oficial para el objeto 2003 VB12, un planetoides distante con una órbita muy elíptica. (p. 237)

circuito en serie: circuito en el cual la corriente eléctrica tiene una sola trayectoria para seguir. (p. 407)

zona de sombra: “zona muerta” entre 105 y 140 grados del epicentro de un terremoto, donde nada es registrado sobre un sismograma. (p. 371)

volcán de escudo: or capas de lava basáltica que fluyeron libremente a alta temperatura. (p. 377)

máquina simple: máquina que realiza el trabajo con un solo movimiento: palanca, polea, rueda y eje, plano inclinado, tornillo y cuña. (p. 166)

reacción de un solo desplazamiento: reacción química en la cual un elemento reemplaza a otro elemento en un compuesto. (p. 731)

fricción deslizando: fuerza de fricción que se opone al movimiento de dos superficies que se deslizan entre sí. (p. 84)

sociedad: grupo de personas que comparten valores y creencias similares. (p. 46)

soil/strong base

- soil:** mixture of weathered rock, decaying organic matter, water, and air that overlies bedrock and is capable of supporting plant life. (p. 650)
- solar eclipse:** occurs during new moon, when the Moon passes directly between the Sun and Earth, casting a shadow on part of Earth. (p. 201)
- solenoid:** a wire wrapped into a cylindrical coil. (p. 432)
- solstice:** occurs twice yearly (June and December), when the Sun reaches its greatest distance north or south of the equator. (p. 195)
- ★ **solubility:** maximum amount of a solute that can be dissolved in a given amount of solvent at a given temperature. (p. 759)
- solute:** in a solution, the substance being dissolved. (p. 753)
- solution:** homogeneous mixture that remains constantly and uniformly mixed and has particles that are so small they cannot be seen with a microscope. (pp. 556, 752)
- solvent:** in a solution, the substance in which the solute is dissolved. (p. 753)
- specific heat:** amount of thermal energy needed to raise the temperature of 1 kg of a material 1°C. (p. 257)
- spectroscope:** device that disperses light into its component wavelengths, using a prism or diffraction grating. (p. 822)
- speed:** distance an object travels per unit of time. (p. 71)
- sphere:** three-dimensional, round object whose surface is the same distance from the center in all directions. (p. 186)
- standing wave:** a wave pattern that forms when waves of equal wavelength and amplitude, but traveling in opposite directions, continuously interfere with each other; has points called nodes that do not move. (p. 308)
- static electricity:** the accumulation of excess electric charge on an object. (p. 392)
- static friction:** frictional force that prevents two surfaces from sliding past each other. (p. 84)
- streak:** color of a mineral in powdered form; helps identify a mineral and can be observed by rubbing a mineral on a white porcelain tile. (p. 611)
- strong acid:** any acid that dissociates almost completely in solution. (p. 771)
- strong base:** any base that dissociates completely in solution. (p. 772)

suelo/base fuerte

- suelo:** mezcla de rocas degradadas, materia orgánica en descomposición, agua y aire que yace sobre el lecho rocoso y que es capaz de soportar la vida vegetal. (p. 650)
- eclipse solar:** ocurre durante la luna nueva, cuando la Luna pasa directamente entre Sol y la Tierra, proyectando una sombra sobre una parte de la Tierra. (p. 201)
- solenoid:** cable envuelto en forma de bobina cilíndrica. (p. 432)
- solsticio:** fenómeno que ocurre dos veces al año (junio y diciembre), cuando el sol alcanza su mayor distancia al norte o al sur del ecuador. (p. 195)
- solubilidad:** máxima cantidad de soluto que puede ser disuelto en una cantidad dada de solvente a una temperatura determinada. (p. 759)
- solut:** en una solución, la sustancia que está disuelta. (p. 753)
- solución:** mezcla homogénea que permanece constante y uniformemente mezclada y que tiene partículas tan pequeñas que no pueden ser vistas en un microscopio. (pp. 556, 752)
- solvente:** en una solución, la sustancia en la cual se disuelve el soluto. (p. 753)
- calor específico:** cantidad de energía térmica necesaria para aumentar un grado centígrado la temperatura de un kilogramo de material. (p. 257)
- espectroscopio:** dispositivo que dispersa la luz en las longitudes de onda que la componen, utilizando un prisma o rejilla de difracción. (p. 822)
- velocidad:** distancia que recorre un objeto por unidad de tiempo. (p. 71)
- esfera:** objeto redondo tridimensional cuya superficie está a la misma distancia desde el centro hacia todas las direcciones. (p. 186)
- onda estacionaria:** patrón de una onda que se forma cuando ondas con la misma longitud de onda y amplitud, pero que viajan en direcciones opuestas, interfieren continuamente entre sí; tiene puntos llamados nodos que no se mueven. (p. 308)
- electricidad estática:** la acumulación del exceso de carga eléctrica en un objeto. (p. 392)
- fricción estática:** fuerza que evita que dos superficies en contacto se deslicen una sobre otra. (p. 84)
- veta:** color de un mineral en forma de polvo; ayuda a identificar un mineral y puede observarse al frotar un mineral sobre una losa de porcelana blanca. (p. 611)
- ácido fuerte:** cualquier ácido que se disocie casi por completo en una solución. (p. 771)
- base fuerte:** cualquier base que se disocie completamente en una solución. (p. 772)

strong force/third law of motion

strong force: attractive force that acts between protons and neutrons in an atomic nucleus. (p. 878)

subduction: occurs when lithospheric plates converge and the edge of one plate is forced downward beneath another; recycles old lithosphere. (p. 359)

substance: element or compound that cannot be broken down into simpler components and maintain the properties of the original substance. (p. 552)

subtropical high: persistent, relatively stationary, high-pressure system. (p. 525)

sunspots: cool, darker areas of the Sun's photosphere. (p. 827)

supersaturated solution: any solution that contains more solute than a saturated solution at the same temperature. (p. 762)

suspension: heterogeneous mixture containing a liquid in which visible particles settle. (p. 558)

synthesis reaction: chemical reaction in which two or more substances combine to form a different substance. (p. 731)

fuerza de atracción/tercera ley de movimiento

fuerza de atracción: fuerza de atracción que actúa entre protones y neutrones en un núcleo atómico. (p. 878)

subducción: fenómeno que ocurre cuando las placas litosféricas convergen y el borde de una placa es forzado a pasar por debajo del otro; recicla la litosfera antigua. (p. 359)

sustancia: elemento o compuesto que no se puede descomponer en componentes más simples y que mantiene las propiedades de la sustancia original. (p. 552)

alto subtropical: sistema persistente de alta presión relativamente estacionario. (p. 525)

manchas solares: áreas frías y más oscuras de la fotosfera solar. (p. 827)

solución sobresaturada: cualquier solución que contenga más solutos que una solución saturada a la misma temperatura. (p. 762)

suspensión: mezcla heterogénea que contiene un líquido en el cual las partículas visibles se sedimentan. (p. 558)

reacción síntesis: reacción química en la cual se combinan dos o más sustancias para formar una sustancia diferente. (p. 731)

T

technology: application of science to help people. (p. 13)

temperature: measure of the average kinetic energy of all the particles in an object. (p. 255)

temperature inversion: an increase of temperature with height, resulting in very stable air that resists the rising needed for cloud formation or dispersal of air pollution. (p. 519)

texture: describes the size and arrangement of rock components and can help indicate how a rock formed. (p. 617)

theory: explanation of things or events that is based on knowledge gained from many observations and investigations. (p. 12)

thermal energy: sum of the kinetic and potential energy of the particles in an object; is transferred by conduction, convection, and radiation. (p. 256)

third law of motion: states that when one object exerts a force on a second object, the second object exerts a force on the first object that is equal in strength and in the opposite direction. (p. 113)

tecnología: aplicación de la ciencia en beneficio de la población. (p. 13)

temperatura: medida de la energía cinética promedio de todas las partículas en un objeto. (p. 255)

inversión de temperatura: incremento de la temperatura con la altura, resultando en aire muy estable que resiste la elevación necesaria para la formación de nubes o dispersión de la contaminación del aire. (p. 519)

textura: patrón que describe el tamaño y disposición de los componentes rocosos y que puede ayudar a indicar cómo está formada la roca. (p. 617)

teoría: explicación de las cosas o eventos que se basa en el conocimiento obtenido a partir de numerosas observaciones e investigaciones. (p. 12)

energía térmica: suma de la energía cinética y potencial de las partículas en un objeto, la cual se transfiere por conducción, convección y radiación. (p. 256)

tercera ley de movimiento: establece que cuando un objeto ejerce una fuerza sobre un segundo objeto, el segundo objeto ejerce una fuerza igual de fuerte sobre el primer objeto y en dirección opuesta. (p. 113)

Glossary/Glosario

tide/ultraviolet waves

tide: rise and fall in Earth's sea level, caused by a giant wave formed by the gravitational pull of the Sun and Moon. (p. 199)

time zone: 15°-wide area on Earth's surface in which the time is the same. (p. 190)

tracer: radioactive isotope, such as iodine-131, that can be detected by the radiation it emits after it is absorbed by a living organism. (p. 804)

transceiver: device that transmits one radio signal and receives another radio signal at the same time, allowing a cordless phone user to talk and listen at the same time. (p. 473)

transform boundary: plate tectonic boundary that exists as a large fault, or crack, along which lithospheric plates move in a horizontal direction. (p. 360)

transformer: device that uses electromagnetic induction to increase or decrease the voltage of an alternating current. (p. 443)

translucent: material that transmits some light but not enough to see objects clearly through it. (p. 327)

transmutation: process of changing one element to another through radioactive decay. (p. 792)

transparent: material that transmits almost all the light striking it so that objects can be clearly seen through it. (p. 327)

transverse wave: wave for which the matter in the medium moves back and forth at right angles to the direction the wave travels; has crests and troughs. (p. 290)

troposphere: lowest layer of Earth's atmosphere where most weather occurs and temperature normally decreases with height. (p. 519)

trough: the lowest points on a transverse wave. (p. 294)

turbine: large wheel that rotates when pushed by steam, wind, or water and provides mechanical energy to a generator. (p. 440)

Tyndall effect: scattering of a light beam as it passes through a colloid. (p. 557)

marea/ondas ultravioleta

marea: elevación y caída del nivel del mar en la Tierra, causadas por una ola gigante formada por la atracción gravitacional del Sol y de la Luna. (p. 199)

zona horaria: área sobre la superficie terrestre de 15° de ancho en la que la hora es la misma. (p. 190)

indicador radiactivo: isótopo radiactivo, tal como el yodo-131, que puede ser detectado por la radiación que emite después de ser absorbido por un organismo vivo. (p. 804)

radio transmisor-receptor: dispositivo que transmite y recibe una señal de radio al mismo tiempo, permitiendo que un usuario de un teléfono inalámbrico pueda hablar y escuchar al mismo tiempo. (p. 473)

límite de transformación: límite de la placa tectónica que existe como una gran falla o grieta, a lo largo del cual las placas litosféricas se mueven en dirección horizontal. (p. 360)

transformador: dispositivo que usa inducción electromagnética para aumentar o disminuir el voltaje de una corriente alterna. (p. 443)

translúcido: material que transmite alguna luz pero no la suficiente para ver claramente los objetos a través del mismo. (p. 327)

transmutación: proceso de cambio de un elemento a otro mediante la descomposición radioactiva. (p. 792)

transparente: material que transmite casi toda la luz, chocándola de tal manera que los objetos pueden ser claramente vistos a través del mismo. (p. 327)

onda transversal: onda para la cual la materia en el medio se mueve hacia adelante y hacia atrás en ángulos rectos respecto a la dirección en que viaja la onda; ésta tiene cresta y depresiones. (p. 290)

troposfera: capa más baja de la atmósfera terrestre donde ocurre la mayoría de los fenómenos climáticos y la temperatura disminuye normalmente con la altura. (p. 519)

depresión: los puntos más bajos en una onda transversal. (p. 294)

turbina: rueda grande que gira al ser impulsada por vapor, viento o agua y que suministra energía mecánica a un generador. (p. 440)

efecto Tyndall: difusión de un rayo de luz al pasar a través de un coloide. (p. 557)

U

ultraviolet waves: electromagnetic waves with wavelengths between about 400 billionths and 10 billionths of a meter. (p. 465)

ondas ultravioleta: ondas electromagnéticas con longitudes de onda entre aproximadamente 10 y 400 billonésimas de metro. (p. 465)

unbalanced forces/weak acid

fuerzas desbalanceadas/ácido débil

unbalanced forces: forces that combine to produce a net force that is not equal to zero and cause the velocity of an object to change. (p. 82)

unconformity: gap in the rock record representing a period of erosion or non-deposition. (p. 671)

uniformitarianism: Hutton's concept that the laws of nature act today as they have in the past. (p. 670)

unsaturated solution: any solution that can dissolve more solute at a given temperature. (p. 671)

Uranus: seventh planet from the Sun; appears blue-green because of atmospheric methane, and its axis of rotation is tilted on its side. (p. 235)

fuerzas desbalanceadas: fuerzas que se combinan para producir una fuerza neta diferente a cero y causan que cambie la velocidad de un objeto. (p. 82)

discordancia: brecha en el registro rocoso que representa un periodo de erosión o falta de deposición. (p. 671)

uniformitarianismo: concepto de Hutton respecto a que las leyes de la naturaleza que actúan hoy día son iguales a las del pasado. (p. 670)

solución no saturada: cualquier solución que puede disolver más solutos a una temperatura determinada. (p. 671)

Urano: séptimo planeta más cercano al Sol; tiene una apariencia verde-azul debido al metano atmosférico, y cuyo eje de rotación está inclinado hacia un lado. (p. 235)

V

variable: factor that can cause a change in the results of an experiment. (p. 9)

★ **vector:** a physical quantity that is specified by both a size and a direction. (p. 71)

★ **velocity:** the speed and direction of a moving object. (p. 73)

Venus: second planet outward from the Sun; has a dense, atmosphere of mostly carbon dioxide and very high surface temperatures. (p. 224)

viscosity: a fluid's resistance to flow. (p. 375)

visible light: electromagnetic waves with wavelengths of 750 to 400 billionths of a meter that can be detected by human eyes. (p. 465)

voltage difference: related to the force that causes electric charges to flow; measured in volts (V). (p. 400)

volume: amount of space occupied by an object. (p. 18)

variable: factor que puede causar un cambio en los resultados de un experimento. (p. 9)

vector: cantidad física que está especificada por un tamaño y una dirección. (p. 71)

velocidad direccional: la rapidez y dirección de un objeto en movimiento. (p. 73)

Venus: segundo planeta más cercano al Sol; tiene una atmósfera densa compuesta principalmente de dióxido de carbono y una temperatura superficial muy alta. (p. 224)

viscosidad: resistencia de un fluido al flujo. (p. 375)

luz visible: ondas electromagnéticas con longitudes de onda entre 400 y 750 billonésimas de metro y que pueden ser detectadas por el ojo humano. (p. 465)

diferencia de voltaje: se refiere a la fuerza que causa que las cargas eléctricas fluyan; se mide en voltios (V). (p. 400)

volumen: espacio ocupado por un objeto. (p. 18)

W

water table: boundary separating the saturated zone from the unsaturated zone. (p. 664)

wave: a repeating disturbance or movement that transfers energy through matter or space. (p. 288)

wavelength: distance between one point on a wave and the nearest point just like it. (p. 295)

weak acid: any acid that only partly dissociates in solution. (p. 771)

tabla de agua: límite que separa la zona saturada de la zona insaturada. (p. 664)

onda: alteración o movimiento repetitivo que transfiere energía a través de la materia o el espacio. (p. 288)

longitud de onda: distancia entre un punto en una onda y el punto semejante más cercano. (p. 295)

ácido débil: cualquier ácido que solamente se disocia parcialmente en una solución. (p. 771)

Glossary/Glosario

weak base/X rays

weak base: any base that does not dissociate completely in solution. (p. 772)

weather fronts: zones in which air masses interact. (p. 526)

weathering: process of physical or chemical breakdown of materials at or near Earth's surface, influenced by factors such as the nature of the parent material, climate, and time. (p. 646)

wedge: simple machine that is an inclined plane with one or two sloping sides. (p. 173)

weight: gravitational force exerted on an object. (p. 106)

westerlies: global winds that blow from the west in the middle latitudes. (p. 524)

wheel and axle: simple machine that consists of a shaft or axle attached to the center of a larger wheel, so that the shaft and the wheel rotate together. (p. 171)

white dwarf: giant star that has lost its outer layers, leaving behind a hot, dense core that continues to contract under gravity. (p. 825)

work: transfer of energy that occurs when a force makes an object move; measured in joules. (p. 154)

base débil/rayos X

base débil: cualquier base que no se disocie completamente en una solución. (p. 772)

frentes climáticos: zonas en las que interactúan las masas de aire. (p. 526)

desgaste: proceso de fraccionamiento físico o químico de materiales en o cerca de la superficie terrestre, influenciado por factores como la naturaleza del material de origen, el clima y el tiempo. (p. 646)

cuña: máquina simple que consiste de un plano inclinado con uno o dos lados en declive. (p. 173)

peso: fuerza gravitacional ejercida sobre un objeto. (p. 106)

vientos del oeste: vientos globales que soplan desde el oeste en las latitudes medias. (p. 524)

rueda y eje: máquina simple que consiste de una barra o eje sujeto al centro de una rueda de mayor tamaño de manera que el eje y la rueda giran juntos. (p. 171)

enana blanca: estrella gigante que ha perdido sus capas externas, dejando un núcleo denso y caliente que continúa contrayéndose bajo la gravedad. (p. 825)

trabajo: transferencia de energía que se produce cuando una fuerza hace mover un objeto y que se mide en julios. (p. 154)

X

X rays: electromagnetic waves with wavelengths between about 10 billionths of a meter and 10 trillionths of a meter, that are often used for medical imaging. (p. 467)

rayos X: ondas electromagnéticas con longitudes de onda entre 10 billonésimas de metro y 10 trillonésimas de metro, las cuales se utilizan con frecuencia para producir imágenes de uso médico. (p. 467)

Democritus

Democritus, 581; atomic model of, 582

Density, 19; calculating, 21 *act*, 33 *act*; of Earth, 187; measuring, 19, 19 *lab*, 20

Dependent variable, 9

Deposition, 654; by glaciers, 659, 659; by mass wasting, 662; of soil, 654, 656, 656; in streams, 656, 656; by wave action, 661; by wind, 660, 660

Derived unit, 19

Desert(s), 535, 660, 660; and convention currents, 268, 269; and wind, 658, 659

Desertification, 538

Desert pavement, 660

Design Your Own, Become a Bond Breaker, 710–711; Blocking Noise Pollution, 344–345; Comparing Motion from Different Forces, 88–89; Comparing Series and Parallel Circuits, 414–415; Controlling Electromagnets, 446–447; Developing a Measurement System, 28–29; Investigating Microclimate, 540–541; Measuring the Conservation of Mass, 568–569; Swinging Energy, 144–145; Testing Unknown Soil Samples for Life, 242–243

Destructive interference, 306, 307, 307. *See also* Interference

Detrital sedimentary rock, 626, 626–627; classification of, 627; composition of, 627; textures of, 626

Detritus, 626

Developing countries, 42, 42

Dew, 263, 263

Diameter, of Earth, 187

Diamond, hardness of, 611; speed of light in, 460

Differential weathering, 649, 649, 661. *See also* Weathering

Diffraction, 304, 304–305, 305 *act*; of radio waves, 305; and wavelength, 305, 305

Diffuse reflection, 328, 328

Diffusion, 261

Dinitrogen oxide, 689

Dinosaurs, extinction of, 536 *act*

Diorite, 620, 621

Direct current (DC), 442

Discontinuity, 371; Mohorovicic, 370, 371, 371

Discovery, scientific, 38

Discovery space shuttle, 820

Disease(s), causes of, 38; contagious, 39, and HIV, 42, 42 *act*; and microorganisms, 38; plague, 38, 38, 39, 120; prevention of, 38, 38, 39; vaccines for, 44

Disk magnet, 425. *See also* Magnet(s)

Displacement, 71; calculating, 93 *act*; and distance, 71, 71

Dissociation, of acids, 768, 768, 771, 771, 772, 772; of bases, 768, 768, 772

Dissolving, 755, 755–758, 776–777 *lab*; and amount of solid, 755, 755, 759, 759; and amount of surface area, 756, 756, 756 *lab*, 757 *act*; rate of, 756–758; and stirring, 756; and temperature, 758, 761

Distance, calculating, 75 *act*, 326 *act*, 337 *act*, 349 *act*; and displacement, 71, 71; and force, 161, 161; graphing against time, 74, 74, 75; horizontal and vertical, 109, 109; large, measuring, 220; measuring, 17, 17, 17 *act*, 20, 156

Distillation, 562–563; of water, 551 *lab*, 562–563, 563

Distributaries, 657, 657

Divergence, 356

Divergent boundary, 358, 358, 376

Dolphin, and echoes, 301

Domain, magnetic, 429, 429, 430 *act*

Dome(s), in geologic mapping, 674, 674

Doppler effect, 323–324, 324, 837

Double-displacement reaction, 732, 732. *See also* Chemical reaction

Downbursts, 527

Downdrafts, 527

Drainage basin, 655, 655

Drought, 42

Drum, 308

Dry-cell battery, 402, 402. *See also* Battery

Duct, 272, 272

Ductility, 570

Dune(s), 660, 660

Dust bowl, 542

Dust storm, 527

Dwarf elliptical galaxy, 832, 833, 833, 834, 834. *See also* Galaxies

Dwarf star, 824, 825. *See also* Star(s)

Dynamite, 734, 734

Early civilizations, 201 *act*

Earplugs, 322

Ear protectors, 307 *act*

Earth, 225, 225; atmosphere of, 108 *act*, 224, 225, 466, 466, 518–522. *See* Atmosphere; average density of, 187; axis of, 188, 193, 193; carbon dioxide in atmosphere of, 492, 492; as center of solar system, 218, 218; circumference of, 187; comparing to other planets, 189 *act*; core of, 371, 371, 372, 372, 427; crust of, 608–609, 609, 613–614, 617, 619. *see* Crust; diameter of, 187; distance to Sun, 17 *act*, 187, 188, 220, 280 *act*; fault lines of, 82 *act*; geologic time on. *see* Geologic time; gravitational acceleration of, 106, 106–107; gravitational force of, 97 *lab*, 104, 106, 107, 107, 108, 108 *act*, 256; gravity on, 187; heliocentric longitude for, 244; interior of, 370, 370–372, 371, 372; internal layers of, 372, 372; life on, 225, 239, 784, 784; magnetic field of, 188, 188 *act*, 427, 427, 829; magnetic poles of, 188, 427; mantle of, 372, 620; mass of, 187; measuring, 186, 186, 187; measuring time on, 190, 190–192, 191, 192; Moon's effects on, 184, 198 *act*, 198–199, 199; motion of, 71, 90 *act*, 190, 190, 192, 192, 524, 524; orbit of, 188–189, 192, 192, 193, 219; ozone layer of, 466, 466;

Earth materials

- physical properties of, 187; as penumbra of, 202, 202; planet, 189, 189; revolution of, 192, 192; rotation of, 190, 192, 524; seasons on, 193, 193–195, 194, 195 *lab*; shape of, 186, 186–187; similarities to Mars, 189; similarities to Venus, 189; size of, 185 *lab*, 186, 187; as sphere, 186, 187; stars visible from, 817 *lab*, 818, 818; temperature on, 189, 225; umbra of, 202, 20; uniformity of, 371; velocity of, 77
- Earth materials**, 606–641, 607 *lab*; clay, 625, 631, 636–638; freezing point of, 618; igneous rocks, 617–623, 622 *act*; melting point of, 618; metamorphic rock, 630, 630–634, 631 *act*, 631, 632 *act*, 633; minerals, 608–616, 612 *lab*, 615 *act*, 616 *lab*; sedimentary rock, 624–629, 627 *act*, 628 *lab*

Era, 672

Erosion, 654; by glaciers, 658 *act*, 658, 658–659, 659; by mass wasting, 662, 662; by running water, 655, 655–657, 656 *lab*, 656, 657; of soil, 652; by streams, 655, 659; by wave action, 661; by wind, 660

Eruption, volcanic, 622

Eruptive products, 347–375, 375 *lab*, 377

Eruptive styles, 375–376, 376

Ethanol, chemical formula for, 689

Ethics, in science, 50, 50 *act*

Europa (Jupiter's moon), 232, 233, 233, 240, 240

Evaporation, 262; in chemical sedimentary rocks, 628; in global water cycle, 522, 522; minerals from, 613; and plants, 522; and sedimentary rock, 628, 628 *lab*; in water cycle, 662

Evaporites, 628 *lab*

Everglades, rainfall in, 533

Exergonic reaction, 736, 736, 738, 738. *See also* Chemical reaction

Exothermic reaction, 738, 738. *See also* Chemical reaction

Expansion joint, 264, 264

Experiment(s), 8–10; and communication, 10, 10; controls in, 9; drawing conclusions in, 10; objectivity in, 10; testing hypothesis in, 8; variables in, 9

Extinction, 118, 536 *act*

Extra Math Problems, 879–890

Extrasolar planets, 222

Extraterrestrial life, 239–241

Extrusive igneous rock, 622; 620–623, colors of, 621, composition of, 621, 621; gases in, 623; textures of, 620, 621, 622, 622

Eye(s), 335, 335–336. *See also* Vision problems; lens of, 54 *act*, 335, 335; and light, 340–341, 341

Fahrenheit temperature scale, 21, 255, 255 *act*

Fall equinox, 194, 195

Falling, free fall, 106, 106, 108, 108; and gravity, 97 *lab*; and terminal velocity, 86, 86

Family (group) of elements, 592, 594

Farsightedness, 336, 336

Fault(s), 356, 360, 364, 373

Fault lines, 82 *act*

Faunal succession, principle of, 671

Feldspar, cleavage of, 610; in Earth's crust, 614; in gabbro, 620; in granite, 620; hardness of, 611, plagioclase, 614, 618, 620, 633; potassium, 620; and weather, 626; weathering of, 649, 649. *See also* Weathering

Feldspar group silicates, 614

Fermi, Enrico, 801, 810, 810

Fermi National Accelerator Laboratory, 580, 580

Fertilizer, 9

Field(s), electric. *see* Electric field; magnetic. *see* Magnetic field

Filament, 159, 403, 403, 404, 553

Filter, colored, 339–340, 340

Finger Lakes, 659

Fireworks, 728

First-class lever, 166, 167, 167, 168, 169, 169. *See also* Lever

First law of motion, 98–101, 99, 99 *lab*, 100, 101

First law of thermodynamics, 274, 274

Fish ladder, 503, 503

Fission, nuclear, 141, 141, 496, 496, 720, 801, 801–802, 802, 802 *act*, 804 *act*

Fission products, 496

Fixed pulley, 169, 169. *See also* Pulley

Flammability, 563

Flare, solar, 828, 828

Flash flood, 658

Flashlight, 403

Fleece, 270

Flight test engineer, 56 *act*

Flooding, 649, 654, 655; flash, 658

Force(s)

Floodplain, 657, 657

Florida, rainfall in, 533

Fluid(s), expansion of, 267; heat as, 7, 7

Fluorescent materials, 465, 465

Fluorine-18, 805

Fluorite, chemical formula for, 609; hardness of, 611

Flute, 308

FM radio, 470, 470, 471

Focal length, 332, 333, 333, 334, 336 *lab*

Focal point, 332, 333, 333, 334

Focus, 363, 369, 369

Focus depth, of earthquakes, 363, 363

Fog, 526, 556, 557, 557

Fold(s), 675, 675

Foldables, 5, 31, 37, 61, 69, 91, 97, 121, 127, 147, 153, 179, 185, 211, 217, 245, 253, 281, 287, 313, 319, 353, 383, 391, 417, 423, 449, 455, 479, 485, 511, 517, 543, 551, 571, 577, 601, 607, 639, 645, 679, 687, 713, 719, 745, 751, 779, 785, 811, 817, 843

Folded mountains, 359

Foliated rock, 631, 631, 632

Foliated textures, 631–632

Food(s), acids in, 764, 764; as basic need, 42, 42; and biotechnology, 45; energy from, 143 *act*; as mixture, 554, 554, 555, 556, 556; periodic table of, 597 *lab*; salt in, 700; sugar in, 700

Food chain, and energy, 139 *act*

Forced-air heating system, 272, 272

Force(s), 81; and acceleration, 87 *lab*, 101, 102 *act*, 103, 103; action and reaction, 113, 113–114; balanced, 82, 82; calculating, 111 *act*, 159 *act*, 165 *act*; centripetal, 110, 110 *lab*, 110–111; changing direction of, 161, 161; different, comparing motion from, 88–89 *lab*; and distance, 161, 161; electric. *see* Electric force; electromagnetic, 104; and fault lines, 82 *act*; friction. *see* Friction; gravitational. *see* Gravity; input. *see* Input force; inside atom, 787, 787–788, 788; and machine, 160, 160, 161, 161,

Forest(s)

162, 162, 162 *lab*, 165, 165 *act*;
magnetic, 424; measuring, 156;
and motion, 81, 81–83; multiply-
ing, 162 *lab*; net, 82, 82, 86 *act*,
103, 103 *act*; nuclear, 104; output.
see Output force; strong, 787,
787–788, 788, 789 *lab*; unbal-
anced, 82, 82–83, 99; weak, 793;
and work, 155, 155, 156, 156 *act*,
157, 165, 165 *act*

Forest(s). *See* Rain forests; loss of,
522, 537

Formula. *See* Chemical formula

Fossil(s), 671–672; correlation of,
671, 671; in detrital sedimentary
rock, 627; and geologic time,
672; index, 671; matching on
different continents, 355, 355

Fossil fuels, 487–493; alternatives
to, 506, 506; coal, 490–491, 492,
629, 629; conserving, 493; costs
of using, 492, 492; decline in
production of, 493, 493; effi-
ciency of converting, 492; for-
mation of, 488; and greenhouse
gases, 742–743 *lab*; making, 487,
488; natural gas, 131, 131, 488,
490; petroleum (oil), 488, 489,
491, 492, 493, 493; pollutants
released by, 492, 492; as source
of carbon dioxide, 51 *lab*

Foundations, private, 47

Fraction(s). *See also* Applying
Math; Math Skill Handbook;
using, 481 *act*, 795 *act*

Fractional distillation, 489

Fracture, 610

Free fall, 106, 106, 108, 108

Freezing, 262

Freezing point, of water, 20, 21, 21;
of minerals, 618

Frequency, 295–296; calculating, 299
act, 315 *act*, 349 *act*; of carrier
waves, 470, 470; of electromag-
netic waves, 460, 462, 462; natu-
ral, 309; for radio, 470, 476–477
lab; of sound waves, 323, 323; and
wavelength, 296, 296

Freshwater, 663, 678; availability of,
662; and life, 668; and pollution,
668; protecting, 668

Friction, 83–84, 110, 140, 165, 165;
causes of, 83, 83; comparing, 83

lab; rolling, 84; sliding, 84, 84, 86
act, 123 *act*; static, 84, 84; and
wave formation, 292

Front, weather, 526, 526

Frost wedging, 647

Fuel(s). *See also* Energy; Fossil
Fuels; Gasoline; alternative, 506;
biomass, 506; nuclear, 495, 495

Fuel efficiency, 53

Fuel gauge, 435, 435

Fuel rods, 495, 495, 496, 498, 498,
499

Fulcrum, 166, 166, 167, 167, 168

Full moon, 200, 200

Furnace, 272, 273

Fuse, 409, 410, 410

Fusion, heat of, 262; of hydrogen
and helium, 221, 823, 827;
nuclear, 141, 141 *act*, 500, 500,
720, 803, 803, 803 *lab*; in star,
823, 824, 827

Gabbro, 620, 621

Galaxies, 831–835; center of, 835,
835; cluster of, 831, 837 *act*; col-
liding, 816, 833, 833; dwarf, 832,
833, 834; elliptical, 832, 832; for-
mation of, 833; irregular, 832,
832; sizes of, 832, 834; spiral,
831, 832–833, 834, 834–835

Galilei, Galileo, 120, 219, 220, 232,
233, 233, 821

Galileo space probe, 233, 240

Galle, Johann, 235

Galvanometer, 434–435, 435

Gamma rays, 462, 467, 793, 806

Gamow, George, 837 *act*

Ganymede (Jupiter's moon), 232,
233

Garnet, 631

Gas(es), 260, 261; and atmospheric
pressure, 524; condensation of,
263, 263; conduction in,
278–279 *lab*; convection in, 271
lab; dissolving, 755; greenhouse,
742–743 *lab*; in magma, 623;
natural. *see* Natural gas; noble,
690, 690; solubility of, 763, 763;
speed of sound in, 321; thermal
expansion of, 253 *lab*, 265, 265;
as thermal insulator, 270; trace,

518, 537; in volcanic eruptions,
375

Gasoline, alternative fuels to, 506,
506; calculating mileage, 63 *act*;
and environment, 48; making,
487

Gear, 172, 172

PERIODIC TABLE OF THE ELEMENTS

Columns of elements are called groups. Elements in the same group have similar chemical properties.

1	2	3	4	5	6	7	8	9
Hydrogen 1 H 1.008								
Lithium 3 Li 6.941	Beryllium 4 Be 9.012							
Sodium 11 Na 22.990	Magnesium 12 Mg 24.305							
Potassium 19 K 39.098	Calcium 20 Ca 40.078	Scandium 21 Sc 44.956	Titanium 22 Ti 47.867	Vanadium 23 V 50.942	Chromium 24 Cr 51.996	Manganese 25 Mn 54.938	Iron 26 Fe 55.845	Cobalt 27 Co 58.933
Rubidium 37 Rb 85.468	Strontium 38 Sr 87.62	Yttrium 39 Y 88.906	Zirconium 40 Zr 91.224	Niobium 41 Nb 92.906	Molybdenum 42 Mo 95.94	Technetium 43 Tc (98)	Ruthenium 44 Ru 101.07	Rhodium 45 Rh 102.906
Cesium 55 Cs 132.905	Barium 56 Ba 137.327	Lanthanum 57 La 138.906	Hafnium 72 Hf 178.49	Tantalum 73 Ta 180.948	Tungsten 74 W 183.84	Rhenium 75 Re 186.207	Osmium 76 Os 190.23	Iridium 77 Ir 192.217
Francium 87 Fr (223)	Radium 88 Ra (226)	Actinium 89 Ac (227)	Rutherfordium 104 Rf (261)	Dubnium 105 Db (262)	Seaborgium 106 Sg (266)	Bohrium 107 Bh (264)	Hassium 108 Hs (277)	Meitnerium 109 Mt (268)

Element — Hydrogen
 Atomic number — 1
 Symbol — H
 Atomic mass — 1.008
 State of matter — Gas

The first three symbols tell you the state of matter of the element at room temperature. The fourth symbol identifies elements that are not present in significant amounts on Earth. Useful amounts are made synthetically.

Rows of elements are called periods. Atomic number increases across a period.

The arrow shows where these elements would fit into the periodic table. They are moved to the bottom of the table to save space.

Lanthanide series

Actinide series

Cerium 58 Ce 140.116	Praseodymium 59 Pr 140.908	Neodymium 60 Nd 144.24	Promethium 61 Pm (145)	Samarium 62 Sm 150.36
Thorium 90 Th 232.038	Protactinium 91 Pa 231.036	Uranium 92 U 238.029	Neptunium 93 Np (237)	Plutonium 94 Pu (244)

The number in parentheses is the mass number of the longest-lived isotope for that element.

Metal

Metalloid

Nonmetal

The color of an element's block tells you if the element is a metal, nonmetal, or metalloid.

Visit fl.gpscience.com for updates to the periodic table.

10			13	14	15	16	17	18
			Boron 5 B 10.811	Carbon 6 C 12.011	Nitrogen 7 N 14.007	Oxygen 8 O 15.999	Fluorine 9 F 18.998	Helium 2 He 4.003
			Aluminum 13 Al 26.982	Silicon 14 Si 28.086	Phosphorus 15 P 30.974	Sulfur 16 S 32.065	Chlorine 17 Cl 35.453	Neon 10 Ne 20.180
Nickel 28 Ni 58.693	Copper 29 Cu 63.546	Zinc 30 Zn 65.409	Gallium 31 Ga 69.723	Germanium 32 Ge 72.64	Arsenic 33 As 74.922	Selenium 34 Se 78.96	Bromine 35 Br 79.904	Argon 18 Ar 39.948
Palladium 46 Pd 106.42	Silver 47 Ag 107.868	Cadmium 48 Cd 112.411	Indium 49 In 114.818	Tin 50 Sn 118.710	Antimony 51 Sb 121.760	Tellurium 52 Te 127.60	Iodine 53 I 126.904	Krypton 36 Kr 83.798
Platinum 78 Pt 195.078	Gold 79 Au 196.967	Mercury 80 Hg 200.59	Thallium 81 Tl 204.383	Lead 82 Pb 207.2	Bismuth 83 Bi 208.980	Polonium 84 Po (209)	Astatine 85 At (210)	Xenon 54 Xe 131.293
Darmstadtium 110 Ds (281)	Roentgenium 111 Rg (272)	Ununbium * 112 Uub (285)		Ununquadium * 114 Uuq (289)				Radon 86 Rn (222)

* The names and symbols for elements 112–114 are temporary. Final names will be selected when the elements' discoveries are verified.

Europium 63 Eu 151.964	Gadolinium 64 Gd 157.25	Terbium 65 Tb 158.925	Dysprosium 66 Dy 162.500	Holmium 67 Ho 164.930	Erbium 68 Er 167.259	Thulium 69 Tm 168.934	Ytterbium 70 Yb 173.04	Lutetium 71 Lu 174.967
Americium 95 Am (243)	Curium 96 Cm (247)	Berkelium 97 Bk (247)	Californium 98 Cf (251)	Einsteinium 99 Es (252)	Fermium 100 Fm (257)	Mendelevium 101 Md (258)	Nobelium 102 No (259)	Lawrencium 103 Lr (262)

Physical Science with Earth Science

Unit 1 Science and Technology

- 1 The Nature of Science
- 2 Science, Technology, and Society

Unit 2 Motion, Forces, and Energy

- 3 Motion, Acceleration, and Forces
- 4 The Laws of Motion
- 5 Energy
- 6 Work and Machines
- 7 The Earth-Moon-Sun System
- 8 The Solar System

Unit 3 Energy in Motion

- 9 Heat and States of Matter
- 10 Waves
- 11 Sound and Light
- 12 Earth's Internal Processes

Unit 4 Forms of Energy

- 13 Electricity
- 14 Magnetism
- 15 Electromagnetic Radiation
- 16 Energy Sources
- 17 Weather and Climate

Unit 5 Matter and Earth Materials

- 18 Classification of Matter
- 19 Properties of Atoms and the Periodic Table
- 20 Earth Materials
- 21 Earth's Changing Surface

Unit 6 Interactions of Matter

- 22 Chemical Bonds
- 23 Chemical Reactions
- 24 Solutions, Acids, and Bases
- 25 Nuclear Changes
- 26 Stars and Galaxies
